This wattmeter has full scale power readings of 10, 100, and
1000 watts. LARGE dual meters -- one reads forward power
and one reads reflected power -- both at the same time.
It has a remote sensor, with about 3 feet of cable to connect
to the meter itself.
This particular meter works fine, and looks very, very nice.
I can not find a scratch on it. It is still in its original box. $55

Diamond SX-100 Wattmeter / SWR Bridge
This meter has scales of 30 W, 300 W, and 3000 W.
It is for use from 1.6 thru 60 MHz, so is ideal for some
of the modern HF rigs that include 6 meters on them.
It has a fairly large meter that can be backlit if 12 V DC is
applied. It will also read either peak or average power,
and even includes an off switch.
This particular meter works fine, and looks like new.
Not a scratch on it. It is in its original plastic in the
original box, with paper work for $90.

Radio Works T-6 VHF Isolator
This unit is designed for VHF frequencies, and provides
isolation to keep RF where it belongs, and out of your
shack. The purpose of this device is to "decouple" the
feedline from all of the things in your shack, so that the
RF would not get in places it did not beyond. To put it
another way, this device might help keep RF out of your
computer, as an example.
This one is out of the package, but has never been on
the air. $30

Coax connectors and adapters:
Prices are per connector. Several of each are available.
These are NOS (have not been used).

BNC male
standard type - $2
crimp on type - $3

Chassis mount BNC female
square mount (uses 4 screws) - $3
screw in type - $4

BNC 90 degree - female to male - $3

BNC "T" - two female and one male - $4

Antenna adapter to fit the BNC connector on the HT
and provide an SO-239 connector that will permit
a PL-259 to be attached. (BNC male to UHF female) $5

UHF Male (PL-259) to BNC female (opposite of above) $5

UHF double female "Barrel connector" (two SO-239 together) $3

UHF "T" connector with two female (SO-239) and one male
(PL-259) connection - $5

Prices do not include shipping from Florida.

Thanks.

73,

Ken, W8EK

>>> Basic part of a 1/2 wave vertical antenna is a matching coil at the base

This is what I'm after. Not a centre-fed vertical but a genuine half-wave
(or 5/8th) with the coil assembly.

I wonder how to model this / make one? My antenna books don't mention them.

Callum McCormick
http://www.m0mcx.co.uk/

While others were busy thinking outside the box, I cut it up because I
needed some cardboard for a project I was making.

Subject: Re: [ham-antennas] Half wave CB style verticals

doing a bit of research, I find the Cushcraft Ringo was a 5/8 wave
antenna, not 1/2 wave.
But is is a simple antenna. See:
<http://www.cushcraft.com/amateur/support/instruction-manuals.htm> and
look at the AR10 and AR6 antennas (ten meters and six meters). they did
redesign it a bit from the 11 meter version I had in the 70's. With a
little ingenuity, it would not be too difficult to make a homebrew version.
Or maybe find one that you could get for little or nothing and resurrect
it.
Mine had developed a high resistance leakage on the SO239 assembly. I
could make a replacement of sorts for one that should work.
Easier to match than a half wave IMO. It uses a one turn coil, tapped via

a rod, and the whole antenna is at ground potential, as long as the mount
is grounded.

just looked in the newest HRO catalog, and they still sell the AR10
Ringo. Not sure what the price is though.

5/8 wave is just slightly longer than 1/2 wave = 4/8...

A similar antenna, though harder to make, would be a coaxial sleeve
antenna. Mounting would also be harder. This uses a 1/4 wave whip and a
1/4 wave metal sleeve, fed inside the sleeve.

yesterday, I saw an antenna that I had not seen in years. Made by Avanti,

I forget the model right now, but it acts similar to the coaxial sleeve.
I will do some searching later on and see if I can find a picrure of it.
They also made it in a 3 element beam configuration.
Most 11 meter antennas could be redone for 10 meters eaily enough, and
maybe by adding a bit, would do for 12 meters as well...

Basic part of a 1/2 wave vertical antenna is a matching coil at the base,

fed at a tap on the coil. But many made for 11 meters were using a 5/8
wave design, and maybe a few 3/4 wave.
Some of the older antenna books may have some info in them.
Not needing radials makes it easier to mount in many locations...
YMMV

You might go to the Lowes or Home Depot paint dept. and look at the paint poles. They are telescopic, range from 5 ft colapsed to maybe 20 feet or more. Fibergalss usually.

Search ebay for "military antenna mast". These are 4 foot tall sectional army surplus mast assemblies that were used for wire and a variety of other antennas, and frequently used as tent poles, netting supports and more. They come in fiberglass and aluminum. If you choose fiberglass and want it to be permanent you'll have to paint it with epoxy paint for UV resistance.

I have an aluminum version built to 40 feet. It worked very well and I was able to raise it by myself (if alone, some ingenuity is required since it's guyed every 15 feet). If you raise it alone you'll need to build a "crane" from an 8 foot 2X4.

This may be slightly off topic but has anyone tried using RG6 75ohm line to feed a 5BTV, or any other 50ohm input antenna? I have been thinking of trying it but would like some thoughts from others.

Thanks
Scott

The only thought I have is that when you have an efficient vertical, the impedance is 35 ohms... correct?

So there would be a larger difference from 75 to 35, as opposed to 75 to 35.

4841. Re: [ham-antennas] Re: Ladderline feeding 6BTV

Yahoo group: ham-antennas (2008)
Date: 2008-05-12 14:11:08 UTC
From: danny garvin
Topic: 4826 Message: 4841

I have had a lot of success using RG/6 & RG/11 for dipoles since they are typically 72 to 75 ohms. I used RG/11 to feed a 1/4 wave vertical a year or so back and the lowest SWR I could achieve without a tuner was 1.5-1 which is what should be expected using 75ohm cable to feed a 50 antenna. Being in the cable industry I have rescued more than my share of partial reels of RG/11& RG/6 from the dumpster :).

This may be slightly off topic but has anyone tried using RG6
75ohm line to feed a 5BTV, or any other 50ohm input antenna? I have
been thinking of trying it but would like some thoughts from others.

Thanks
Scott

4842. RG/11& RG/6

Yahoo group: ham-antennas (2008)
Date: 2008-05-12 14:48:53 UTC
From: Rich Schmuke
Topic: 4826 Message: 4842

WB8RIM brings up a good point on saving from the dumpster. I bought, at a small town Friday night local auction, a 500 ft roll of RG-11 type 75 ohm and some RG6 single and double. All three rolls for 3 dollars. The RG-11 has a copper-weld center conductor. Made a stripping block , and I use the 14ga copper-weld for antenna work. The farm boys did not know what to do with it so I got the coax for a dollar a roll. The RG-6 is used for stub filters for field day with the local club.

KD0ZZ , Rich

I am not getting older but having a propagation problem with the neurons in the grey matter.

Any errors in spelling or facts are tramsmission errors

Ya... As the efficient increases, you have a 35 ohm antenna with a vertical. Your findings make sense. Dipoles are 72 ohm, so there you go.

Of course, there are people on this thread a heck of a lot smarter than me that may know more. I am just a fighten Irish displaced in northern Michigan.

4844. Suggestions on Antenna Analyzer

Yahoo group: ham-antennas (2008)
Date: 2008-05-12 18:31:02 UTC
From: N3UJJ (Scott Gillis)
Topic: 4844 Message: 4844

I'm looking to make an investment (in the $500 range) into an Antenna Analyzer and would like feedback, and opinions.

I'm looking at the MFJ 269PRO.

The only difference I can find between it and the NON-PRO is the ears on the case, which I don't think are worth $30.00

I would like something to cover that will cover all the bands/antennas that I work (HF/VHF/UHF)

I have also looked at the miniVNA, which requires a PC/Laptop to use (but does not cover UHF), and the PALSTAR ZM30 Antenna Analyzer (which is HF only)

This is a big investment for me, so any and all feedback would be much appreciated

Thanks in advance

Hello Scott,

Suggestions on Antenna Analyzer

I have the MFJ-259B (non uhf) and I really love it. Yes its big an ugly but it works. I thought hard about the laptop versions but most of the time I am on the road and don't have it (laptop) or want it with me. Look at the reviews on eham.net under Antenna Analyzer if you haven't alreay. I learned a lot there.

I would spend the difference between the pro and non-pro versions to get
a pelican case to carry the non-pro in.

Understand that on UHF the 269 is not a full featured analyzer. It is
only a self signal generated SWR meter. It doesn't do any of the other
functions that are available at the lower frequencies. It also has a
design defect that if you have the UHF switch depressed when you power
it up you will blow it up.

With those limitations in mind it is a pretty handy tool for the price.

WOW !!!!!

So what would be a good analyzer for 70cm?

It's starting to look like for the "Best bang for the Buck" is going to be the Aim-4170 from Array Solutions.

Thanks, Jim (K6JMG) for pointing me to their website

AIM does 0-170Mhz, but if your pockets are deep enough it would be
fantastic to have one that plots the range like that.

I own the 269 MFJ myself, it's handy to have for sure, but I sure
would like one that sweeps the range and plots it for me to 'see' what
the antenna is doing as a full picture.

Can the MFJ 269 be connected to your rig/antenna system for constant monitoring, or is it just made for portable tuning when first setting up your system or doing maintenance?

Most of the new HF/50M rigs have built in SWR and power meters. How good they are is debatable. MFJ, Daiwa and probably others make cross needle swr/power meters for 2m/440.

This is what I'm after. Not a centre-fed vertical but a genuine half-wave
(or 5/8th) with the coil assembly.

I wonder how to model this / make one? My antenna books don't mention them.

Callum McCormick

Subject: Re: [ham-antennas] Half wave CB style verticals

doing a bit of research, I find the Cushcraft Ringo was a 5/8 wave
antenna, not 1/2 wave.
But is is a simple antenna. See:
<http://www.cushcraft.com/amateur/support/instruction-manuals.htm> and
look at the AR10 and AR6 antennas (ten meters and six meters). they did
redesign it a bit from the 11 meter version I had in the 70's. With a
little ingenuity, it would not be too difficult to make a homebrew version.
Or maybe find one that you could get for little or nothing and resurrect
it.
Mine had developed a high resistance leakage on the SO239 assembly. I
could make a replacement of sorts for one that should work.
Easier to match than a half wave IMO. It uses a one turn coil, tapped via

a rod, and the whole antenna is at ground potential, as long as the mount
is grounded.

just looked in the newest HRO catalog, and they still sell the AR10
Ringo. Not sure what the price is though.

5/8 wave is just slightly longer than 1/2 wave = 4/8...

A similar antenna, though harder to make, would be a coaxial sleeve
antenna. Mounting would also be harder. This uses a 1/4 wave whip and a
1/4 wave metal sleeve, fed inside the sleeve.

yesterday, I saw an antenna that I had not seen in years. Made by Avanti,

I forget the model right now, but it acts similar to the coaxial sleeve.
I will do some searching later on and see if I can find a picrure of it.
They also made it in a 3 element beam configuration.
Most 11 meter antennas could be redone for 10 meters eaily enough, and
maybe by adding a bit, would do for 12 meters as well...

Basic part of a 1/2 wave vertical antenna is a matching coil at the base,

fed at a tap on the coil. But many made for 11 meters were using a 5/8
wave design, and maybe a few 3/4 wave.
Some of the older antenna books may have some info in them.
Not needing radials makes it easier to mount in many locations...
YMMV

From: comtinker
Topic: 4826 Message: 4860

I think there may be more uses also but likewise I'm afraid to say anything also. There is no doubt there are smarter hams out there than me. Ham radio is all about experimentation!

I have heard of people using it for their 2 meter rigs without any problems but I do not know the details, not have I tried it yet.

On the same subject, there is a 80 meter dipole at my location fed by RG6 and it works great. There again I'm using a tuner also.

Scott

> > I have had a lot of success using RG/6 & RG/11 for dipoles since they are typically 72 to 75 ohms. I used RG/11 to feed a 1/4 wave vertical a year or so back and the lowest SWR I could achieve without a tuner was 1.5-1 which is what should be expected using 75ohm cable to feed a 50 antenna. Being in the cable industry I have rescued more than my share of partial reels of RG/11& RG/6 from the dumpster :).

if I suddenly overcame my acrophobia and wanted to do this, I'd check the established vendors. Their websites will probably have manuals and how-to's you can study.

The only tower name that comes to mind is Rohn, but I have never used a tower, so I'm sure there are more. Google is your friend.

best of luck!

I build and maintain communications towers.

First, what type of tower are you looking to build and
how tall? How much equipment are you planning to put
on it?

How tall do you want to go??? , I made a couple of tilt overs because I am too old to climb. How big of an antenna and rotor (weight wise and wind load) do you want. I can send you pictures and drawings of my tilt overs if needed. You can build a tower without a lot of problems if you have a MIG welder, you have to be a little better to use a stick welder. The tilt units do not require a welder. I have built a Rohn type also a crank up but it has been a few years (25) ago , on my last move when I retired I went to tilt over.

WHY ? ?
Check it one time and unless something changes
don't worry about it.
This is not a CB. Your radio is protected from
over SWR and will just cut back power so it will
not fry your finals.
Life is too simple to worry so much as a Ham.

I would drop the idea of 70cms and stick to all the other bands.
I have a MiniVNA and its tops. Its twice as good as the MFJ and its up gradeable via PC also there is a kit to make it work on Bluetooth also it works with a PDA aswell....

You will pay lots of money to get something which will function on 70cm correctly so forget it and stick to normal bands...

Hi Rich,
I need about 40 foot, I will be hopefully mounting the Crushcraft MA5B (12KG) and a Yaesu G450 C rotator (3.5KG) on the finished tower, I really need a tilt over something that I can handle myself as I too can't climb anymore. I was thinking about two (or more) sections of box steel and fitting them inside each other to work in a telecopic fashion via a winch. Welding is not a problem if it needed.

I'd really appreciate any pictures or drawings you can send me.

> WHY ? ?
> This is not a CB.

Good point.

On the other hand, this hobby isn't CB either, and one of our foundations is to experiment. If you plan to build and tweak UHF antennas, then a good SWR meter or impedance analyzer is good to have access to. (Not necessarily to own. Check if a local ham radio club has one you can borrow.) UHF antennas lend themselves to being built again and again in different configurations (as opposed to build it once and leave it alone).

If you intend to purchase a 70cm antenna, you may never need to measure it.

Do what seems right for you and your wallet.

Andy

hi Dick,

I have one and it works great, not expensive
for a USA made tool from Ripley in CT.

Hi there
was in the same postion as your self which to go for! I was looking at
the same 3 antennas
I went for the MQ
1st Im not a antenna guru thats why I joined this site hi hi
2nd as 3 mates have got them and rate them 100% for small space antennas
3rd the others are dipoles only on 12 & 17,I wanted as much as I could
get out of my space, antenna, and money
4th Since I got my MQ another 3 people I know have also join the MQ
ranks and as far as I know all very pleased. Ive not needed it but I
belive Back up from MQ HQ is very good.
one friend posted this
http://www.mw0jze.inkinkink.net/mq26sr.htm

what ever you get good dx

Where would one look for a "Laptop" version? I have an extra one that I wouldn't mind getting dirty, and if it got broken or damaged, it wouldn't be a great loss. I have another.

Hello Scott,

Suggestions on Antenna Analyzer

I have the MFJ-259B (non uhf) and I really love it. Yes its big an ugly but it works. I thought hard about the laptop versions but most of the time I am on the road and don't have it (laptop) or want it with me. Look at the reviews on eham.net under Antenna Analyzer if you haven't alreay. I learned a lot there.

WOW.$525.00 and they still have the nerve to charge $14.00 for a cable to use it?

I'll stick with my MFJ-259. Does an excellent job on its own. Got a used one for $80.

I like the features of the 4170, but out of my price range. Might be a good investment for a club, but once I get my antenna up, I'm done.

If I hit the lottery though, I'll get us BOTH one.hi hi

Where would one look for a "Laptop" version?

Go to W4RT.com and look at the miniVNA. No its not cheap at $398.00. And yes I agree to stick to the 259b. That being said the laptop versions show graphicly the swr curve and many other things. Small, ease of use, usb powered (not 10 aa bateries) and if your doing digital modes and have a laptop there is a place for them.

4881. Cushcraft R5 sealing of the traps, What sealent to use?

Yahoo group: ham-antennas (2008)
Date: 2008-05-17 22:44:34 UTC
From: Commander John
Topic: 4881 Message: 4881

Hello All
I have a cushcraft R5. I purchased this at a flea market. I have it all cleaned up ready to put it together. But one last step remains. The traps.
I took the capacitor clamp arms off one at a time and cleaned the aluminum with steel wool and replaced the stainless bolts etc. This one had the sealant used by Cushcraft under the Black shrink tubing also under the capacitor clamps too. I cleaned this away, and reinstalled the clamps. The black shrink covering is OK.

I need a sealant to put on the ends of the black shrink tubing to weather proof it. I was thinking of Duco glue which I have. Maybe you got a better idea. If it works and has been proven in the weather so much the better.

You can't get more portable then the end fed
I have a beacon on now with a loop on 7.050.0 but a tube type loop is not
what I call portable.

Par wants $70.00 and that is a 3 band antenna.
Doesn't even have a tuning cap.
I made several in 1 day.
Total cost is appx $10.00.
I use a T-38-2 core a tuning cap 10-270 pf and a 66 foot wire and I can tune
all bands from 40 to 15 meters and have a flat SWR

Par has a single band 30, but you're right homebrew is a possisbility.
I opted for the EF 10-20-40 for my KX-1.

4889. Tak tenna

Yahoo group: ham-antennas (2008)
Date: 2008-05-18 16:25:20 UTC
From: Donal
Topic: 4889 Message: 4889

Hi All...
I was wondering if anyone on the group is using one of these antennas as I have some space on pole mounted 10M AGL on two stand off brackets at the back of the house and was thinking what a waste.

This antenna looks ideal for the pole mentioned above.

With that said, I've heard talk of an 80M version... so should I wait and see or just dive on in and buy the 40M version?

Would there be any advantages over my 6BTV and CW 80 Special?

73 & Good DX

Danny,
Several owners say it's a super antenna.
Others say it's not to hot on 40 meters.
You might try contacting Bill G4KKI at _g4kki.william@.../_
(mailto:g4kki.william@.../)
He put one together for his friend and was testing it against a mag loop.
Their made here in NJ where I live.
I contacted the person but there are no measurements,smith charts or take
off measurements on the antenna.
Just a lot of brag post and I haven't been able to work several hams who say
they have them.
Eham reports look good but they put down the MFJ loop that I have and I use
my MFJ loop inside this steel and concrete apartment and work all kinds of
DX/W/ 5-10 watts/
The designer did say not to use in in my apartment but gave no reason.
Maybe Bill can contact his friend and see how it's working for him.
I don't know if it's directional but when I operate outdoors you can't beat
the end fed with a tiny tuner that fits in your pocket:-)

Well
I'm amazed how many hams refuse to wind 1 core and 1 small tuning cap but will pay that kind of money for a core with no tuning cap and then seal it in the box
I just posted a picture of mine sitting on top of my FT 817 rig.

Joe,
I haven't but one of the members on my list did./
Lot of wire to feed from the end but they work great if you can get half of it vertical and the rest horizontal

From: DAVID MILLER
Topic: 1089 Message: 4896

I need a HF vertical because I live in a hole with very limited space but I don't have antenna restrictions does anyone know of a good vertical antenna for HF that can be mounted up on a pole that doesn't require ground radials?
thanks
David

Cushcraft makes the R5 R6 and R7 verticles they do not require radials. No longer made. I bought my R5 at a swap for $50. It is going up soon. The R7 sells regularly on Ebay for about $200. Check the eham reviews for these antennas. There is a lot of internet info on these antennas. Manuals at cushcraft. Well built.

Hi David,

I have to agree if you have the space go for the Hy-gain. That being said if you have very limited space check out the compromise antenna from comet. The CHA250B from comet does 6m through 80m. Not very well according to reviews on 40m-80m but all multi band antennas have a compromise somewhere.

No my R5 is 20-10 meter as the antennas go newer they go lower there are ones that to 80 and 40 too. Go to cushcraft web site. If they work on 80 they will work poorly. but they do work. you could throw wire and tune it. That works too. somewhat.

I use a Cushcraft R6000 mounted on an 8-foot pole. It has 7 integral radials which I believe are 45 inches long. It is for 6 thru 20 meters including 12 and 17 (& 10 & 15 of course). It has worked well for me, coupled with an amplifier I worked my first DXCC. It is still in their catalog. I use a tuner but they say it is not required. I live at an elevation of 1200 ft. but 100 feet below the highest point in the terrain - so I am not exactly in the clear, but not exactly in a hole either.

From: Bill
Topic: 1089 Message: 4905

Hi Dave, I have the R7 and it doesn't do 80m. Hustler verticals either do 80m or can be made to do 80m with an add-on resonator. Don't know their performance first hand, but owners give mostly good reviews at eHam. Rather subjective. I was considering the 6 band model before being given the R7. I have homebrew windom that does 80m. So far I only do 80m for regional ragchewing, I guess the vertical would get you a lower radiation for longer range. You said you live in a hole. Do you mean a small lot or a section of land lower than the suroundings? I don't know enough yet to know if that would affect the lower radiation angle from a vertical.
Good luck

Bill KC2SUO

> without grounds don't work" however there's plenty of 2, and 70cms antennas
> without a ground that work very well. So careful thought is required here
> before shouting from the rooftops.

I'm not sure if this helps, and for all I know I'm missing what you want to know ...

But my understanding is that half-wave verticals don't need much of a ground plane at all because the half-wave point is the high impedance (minimum current) feed point.

Quarter wave verticals are fed at the maximum current point, and the current into the vertical element must always be matched by an equal but opposite polarity current from the feedpoint going somewhere else (counterpoise, radials, ground plane). If you omit said path, you severely affect that current, and therefore the current into the vertical too.

Since the half-wave's feedpoint is a minimum current point, providing a good *low-impedance* path for the equal-and-opposite current is less important. The coax and supports are always nearby so they act as counterpoises anyway, and small amounts of coupling to nearby objects are more effective, being at the hi-Z feedpoint.

You can also think of the half-wave vertical as a half-wave dipole, but rather than center-fed it is end-fed. If you took an end-fed horizontal half-wave dipole and turned it on its end, it wouldn't need a ground plane any more than it needed a flat plate next to it when it was mounted horizontally.

Many of those 2m and 70cm verticals are mounted on masts so there's your "ground" (doesn't need to be actual earth ground, but just a mirror current path); and if not, the coax feedline may provide a similar counterpoise function that allows the antenna to work semi-normally.

The half-wave's base matching network just needs to effectively transform the coax's low impedance to the half-wave element's high impedance.

Andy

Within the month I hope to have together my first HF station I'm fresh to HF operation. I plan to have the Yaesu FT450 and tune it with the LDG z-100. My question is about the antenna. I'm thinking about the 68' or 102' version G5RV antenna but am reading mixed reviews about them. Will this setup perfom well on 40m 20m and 10m? I think those are the main bands I'll operate. I'm going to install the antenna in the attic.

I didn't have very good luck with a G5rv in the attic. You don't normally have the clearance to get the ladder line properly drooped from the antenna. I also had a lot of problems with RF in the shack from it coupling to the coax. I'm currently running a Alpha Delta DX-CC in my attic which seems to work better on every band than my G5RV did. If you can fit the 102' G5RV you won't have any problem getting the DX-CC in. If 75' is too long take a look at the DX-EE.

Unless you already have the Z100 I would look at the AT100pro instead. Has full auto mode that is lacking on the Z100 and requires no interface to the radio.

At my old QTH I was able to have a antenna for each band.
The good days are gone.
I never used the G5RV but like you have hear pro and con about it.
Just my 2 cents but I would try it and what bands don't seem to good,say 20 meters use a coil loaded short dipole just for that band.
As I said just my 2 cents but I found this link by KC8AON.
Maybe it will be of some help to you.

From: Kirk Morrison
Topic: 4921 Message: 4925

In theory it wont need a tuner on 20, mine wont tune 15, but does well on 40 and ok on 80 and if I short the braid and center of the coax and feed it against ground it does fine on 160, but I have better results with an all band doublet and I hope to have the G5RV replaced soon with a loop and a Windom as I am less than thrilled with the G5RV's performance on several needed bands. YMMV as your near and far field will most likely be different than mine. I am building a couple of wire beams also to make it easier to work DX

4926. thinking of elevated Radials... need help

Yahoo group: ham-antennas (2008)
Date: 2008-05-20 20:43:38 UTC
From: Steve Hunt
Topic: 4926 Message: 4926

Hi all,

I had it all figured out ... when I purchased my Zero-Five 43' Vertical ... laying down as much Radials as possible.

But after 32 Radials (w/lenghts of 15' to 60' and living in NH...the Granit State) the Signals just doesnt seem to get better!!! and honestly, I'm getting tired of laying down another 1000 feet of wire. I mean...I will if I have to... but now I am thinking of...

Cementing a 12' 2.5"OD galv. Pipe... 3 feet into the ground. Mounting the 43' Vertical on top of the Pipe and running an Resonant elevated Radial System! :)

Q: good or bad Idea? and get my butt back to work on the ground radials?

Q: would cutting 16AWG solid copper 1/4 wave lambda Radials work? probably YES

Q: I could run 3ea 135' Radials (160m) about 12' hight into the woods... could I bundle up all Radials? (for other bands) or should they be seperated ... and run in diff. directions? (like the ground Radials).

I mean 3 radials for 160m (135' long) 3 for 80m (64') 3 for 40m (32')... and so forth

To some it might seem like more work...doing elevated radials. BUT I have to remount the Vertical anyway...because while I hammered the 5' 2" Pole into the ground (to mount the Vertical) I noticed that after 3' ... I hit solid Granit and now the Vertical is mounted at a slight 6deg. angle (very ugly looking...and I def. have to fix it)

Anybody have some Advise?
Go elevated or continue w/ground radials (on America's worst Radiating ground)?

your thoughts as allways appreciated
73 Steve, W1CDX

Steve,

I'd contact the folks at Zero-Five. After all, they are the experts.

Rick N6NKN

By the way, I'm very interested as I want to plant a Zero-Five on my
20 acres of decomposed granite in Montana.

How are you quantifying that? Are you talking about RX or TX?

Better compared to what?

Forgot another .02, it's a compromise antenna, so it's going to
perform the best on 20m/40m and be a compromise on the other bands for
the most part. Were you aware of this? Are expectations appropriate?

Elevated radials are the only way to build vertical antennas and not go broke or discouraged in nice hobby.
Three would do plenty, four would be better.
Since this artificial "ground plane" is in theory only the missing half of the vertical dipole - its length does not have to be exactly half wavelength.
Some sources say 5% longer than half wavelength on the lowest frequency will do.
Definitely do not need a separate set for each band!
If you have room, I would try to connect the ends of the radials and check if that makes noticeable difference. I doubt it will.

Recently, searching via Google, I saw a good discussion dealing with sloped (e.g. 45 degree) radials, number of radials that also presented data as far as impedance, efficiency and more.

Just my 10 cents (2 cents not enough for gasoline these days).

hey Rick... yes I should, but I really don't want to bother them unless I have a real problem...

...This is just not having "any" knowledge of Antenna's Hi

I am going to check my Ground Rod again... Try to pound in a second one 10 feet away...(maybe I can somehow bypass that Bolder I hit with the first Pole and groundrod)

Then I'm gonna lay about 24 more shorter (15') Radials... In the upper most section of the Yard.

But before I do anything...I'm gonna wait for my miniVNA to arrive...so I can measure SWR, Impedance and losses ... for all I know It could be a the RG213 feed line. I will see and post here again.

Thanks fer the Tip, Rick

Hi Dave, I have the R7 and it doesn't do 80m. Hustler verticals either do 80m or can be made to do 80m with an add-on resonator. Don't know their performance first hand, but owners give mostly good reviews at eHam. Rather subjective. I was considering the 6 band model before being given the R7. I have homebrew windom that does 80m. So far I only do 80m for regional ragchewing, I guess the vertical would get you a lower radiation for longer range. You said you live in a hole. Do you mean a small lot or a section of land lower than the suroundings? I don't know enough yet to know if that would affect the lower radiation angle from a vertical.
Good luck

Bill KC2SUO

>
> No my R5 is 20-10 meter as the antennas go newer they go lower there are ones that to 80 and 40 too. Go to cushcraft web site. If they work on 80 they will work poorly. but they do work. you could throw wire and tune it. That works too. somewhat.

Steve,

Just curious about how the Zero-Five is working the way you have it set up now? I have heard this is one great antenna for DX!

How does it compare to your Cobra Wire antenna?

Thanks,
Mike

Hi Mike,

right now... the way I have it setup; The Cobra Dipole work's alot better. RX wise it receives about 3-5db stronger, and TX wise...well probably the same (I'm just not satisfied)

I too have read all the good reports on this Antenna, and I do have to say...The Antenna is superbly built, and I am positive that I have a problem with one of my components... I think maybe my radial-plate (Penninger Radial Plate) might be too far off the ground (2"). Maybe I should mount the plate to the pole and let it touch the ground...So I can pull the Radials straight, instead of that little 2" step up to the plate. I will lay down a few more Radials, maybe a dozend or 2, and see what happens.

I just can't believe 50 or so HAMS would falsify the "5.o Reviews" they gave about this Antenna...

But I'm not done with it yet...I will get this thing to work better than it does!

So hang on, Mike
I will report back

I would not worry about a plate 2" off the ground being too low. To test it , set up a 2m vert on your bench, you can see then that it works better with the radials at about 45 degrees than at 90. I would raise it so the radials can go out on an angle. That is how I did my 20m vertical.

right now... the way I have it setup; The Cobra Dipole work's alot better. RX wise it receives about 3-5db stronger, and TX wise...well probably the same (I'm just not satisfied)

I too have read all the good reports on this Antenna, and I do have to say...The Antenna is superbly built, and I am positive that I have a problem with one of my components... I think maybe my radial-plate (Penninger Radial Plate) might be too far off the ground (2"). Maybe I should mount the plate to the pole and let it touch the ground...So I can pull the Radials straight, instead of that little 2" step up to the plate. I will lay down a few more Radials, maybe a dozend or 2, and see what happens.

I just can't believe 50 or so HAMS would falsify the "5.o Reviews" they gave about this Antenna...

But I'm not done with it yet...I will get this thing to work better than it does!

So hang on, Mike
I will report back
Steve, W1CDX

A LOT of the reviews on eham for the zerofive are astroturfing IMO. The claims are just not possible for what the antenna is. I was very curious about that antenna and did some modeling in MMANA and when you wide band tune a vertical that is long for the band, the radiation angle is horrible.

Also, the conditions right now are horrible to test a vertical, the bands have hardly been open lately.

I run a GAP Titan (also a big compromise antenna) in addition to wire antennas and when the band is open, depending upon conditions it can be a real winner. It all depends on how the propagation is working though.

I think you'll notice very different noise characteristics between your wire and the vertical as well.

The vertical shines with the more distant contacts, the bands just haven't really been open for that lately.

The vertical will REQUIRE radials to work. The Radials are the other half of the antenna. Hustler states can be ground mounted with out Radials but, that will only WORK if the soil is moist enough to conduct. I live in a residential area and I use a elevated Hustler 6btv with elevated radials at 10 feet and get excellent results on 40 meters, better than my dipole on 40 meters at 30 feet high (way to low of height for 40 meters). When ground mounted because of the houses around the vertical antenna with radials perfomance was not good.

Hi, Mike,
That is an interesting antenna, I have not seen one like it , to my memory!
My first observation it appears to made for multi-band service for vertical radiation.
With what appears many traps? and the Circle toward the top maybe a toploading for the section.
Now asking for some Clues!!!!
1. Does it have any marking for manufacturer,or is a home-brew unit.
2. Where was it found!, Ham operation area, or commercial?
3. Does it appear to have been made by commercial .?
4. Do you have any measurements available?
5. Measurements that give the distance and length between what appears a traps?
6 This is very interesting and an answer would be nice, I have seen many antennas ,never on like this.
7. The feed? at the base and what appears as insulator to the left, was there an radials??
8 If someone has an analyzer they could see where each resonate freq is??
73 Ken
Hope some will give us the answer.

Greetings all,

I just posted 5 photos in the 'Name That Antenna' folder. This antenna
was discovered by a friend of mine and thus far, neither of us have
been able to ID it. I told him I'd post it here in hopes that someone
would recognize it.

Thanks for the assist.

After a few hours of searching could not find it, it does look like maybe a vry old Hustler 5 band? or perhaps a homebrew cpy:
Check their website for pictures.
73 Ken
5 Band Vertical HF Fixed Station
10, 15, 20, 40, and 75 or 80 Meters
_____
Full band coverage on 10-40 meters (1.6:1 at band edges typical). Solid one inch fiberglass trap forms for optimum mechanical stability. Heavy gauge aluminum with stainless steel hardware construction throughout. Feed with any length 50 ohm coax.
_____
Model 5-BTV
* Electrical:
* SWR: 1.6:1 at band edges
* Bandwidth: up to 100 kHz. on 75/80 meters
* Power: full legal limit CW and SSB 1000 watts
* Mechanical:
* Length: 25'1" long
* Weight: 17 lb.
* Wind Load: 29 lb. at 70 mph
* Mounting:
* Ground mount with or without radials, roof or tower mount with radials.
* Vertical support up to 1.75 in. O.D. pipe.

That looks to be a very early vintage Higain 18HT Hi-Tower vertical antenna.
That ring on the top is a capacity hat to get you on 80 meters
The early antennas had the traps exposed and unprotected like shown in that picture.
I think Higain still makes that antenna but with much better upgrades

Of course, trees come to mind first.

HOWEVER, someone did suggest the use of 20 foot stair railing. I have heard that these can be purchased for $1.50 per foot and come in 20 foot lengths. So for $30.00 you have a 20 foot support.

Just my 10 cents (crude oil is up from 2 cents)

That's what we kind of think too. The vintage seems about right and for some reason Hygain came to mind when looking at it.

The antenna came from FAA surplus. he's trying to figure out what it was hooked to.

The measurements are very similar to current Hygain designs for a 5-band vertical. It has no provision for attaching radials, which may indicate that it was designed for gov't/military applications where there is a VERY large array of buried radials already in place. (You'd be amazed at what's underground at an FAA Comm site!) It certainly does not appear militarized/ruggedized at all however. I agree about the ring being a capacity hat. Current designs use something that looks like the spokes of a wheel, but the intent appears to be the same.

The mounting arrangement only reminded me of a CushCraft Ringo Ranger. everything Hygain has made for as long as I can remember has used U-bolts.

I'll pass this on to him and see if he can put anything else together. Eventually, we'll apply power and tune for maximum smoke!

Thanks all,

Mike

Off the back deck of my house I ran a mast along the top railing and out off the deck about 8 feet. I secured it with multiple bungee cords. Its the top support for my inverted Vee. Its about 35 feet off the ground. Ran ladder line down to the ground and then coax back up to the shack. Each leg is held in place with a 5 gallon paint bucket filled with cement & a 10 foot mast coming out of it. Works like a champ. I have no trees on my lot.

The very early higain antennas didn't have provisions to mount radials.
In fact I remember they said in one of the manuals that if you drive apipe
in the ground and didn't go higher then 4 feet you didn't need radials.
Anyway I updated the adobe thing and now can't open PDF files.
This is the manual for the AV-18HT antenna
Appx 40 pages so it should have pictures.
I tried three times and my lap top hangs up then says Adobe reader not
responding.

I feel like the Hy Tower vertical by Hy Gain/mfj is the
best vertical still, it even does well tuned on 17 meters
as well as 30 meters I don't use it much on 12 but tunes
and works the dx if conditions allow, I can work what
I hear, yea I know we all say that :-)

Here is a url to my installation there are some broken
links so use the links on the left of the page.

ka9zap.com

You can see the mods for 160 meters that I have done,
The Hy Tower is 53' over all in height it
is a 3/8 wave on 20 meters it is collinear on 15,10 meters
so it has a bit of gain on these bands via the decoupling
stubs.
On 40 and 80/75 it is a 1/4 wave.
On 160 it does surprisingly well as a 1/8 wave against
ground vertical with no band width.

Radials are a must for real performance the manual calls
for 6 ground stakes 2 ft from each leg in a circle I have
attached the many 66 ft radials to them then bring this tie
point to the tower legs, as well as soldering some directly
to the heavy wire circle attached at the base of the legs.
What really picked up the system and lowered the feed
point impedance to around 30 ohms was the addition of
aluminum gutter guard captured in 3" stainless steel fender
washers at each ground stake, with NoLox as the butter
in the sandwich. This meant it was necessary
to put a coil across the feed to step up the impedance to
50 ohms.
All the radials are 66' stapled to the ground nothing is buried
the grass has hidden it all from view the radials are not straight
but bent at the end of the straight run the next one is just inside
the last as I went around the base of the antenna out and around.
I have a couple of 130' radials also but most are 66' as you can
see the yard is very small the antenna is not centered but it really
works.
The 160 air core coil is out of MFJ's big tuner it is not the better
edge wound one that they now are using I have
had no problem with it after debugging the system 7 years ago.
After a wind shear storm ripped off a huge tree limb tossed it
at the tower you can see the before and after Rohn tower my only
HF antenna is now the Hy Tower the big draw back is the vertical

noise and cross polarized local signals so on tx it works better
than on rx so some kind of listening antenna fits well with it.
The only 40 meter vertically polarized antenna that came close to or
at times was equal to the Force 12 c4 was the Hy Tower but
the vertical band noise is always going to be an issue on receive.

I have used PVC pipe cut a slot and run the antenna up as a inverted V or two for a standard dipole an guy, I have used the house and trees, and made the dipole from fine wire I have hid the whole dipole in a couple of trees.

How long did the PVC pipe last? I've been thinking about the same idea.

Well with a bit of paint and guying it lasted until I moved about 3 years and it is out in the yard now working in other jobs. I have a piece that lasted outdoors 6 years and still counting. I used 2" ID and it seems to be fine for at least 6 years if guyed or supported if painted. I am in SC so the UV is a consideration but it hasn't been a major problem wind is so guying is or other support to a reasonable heigth is a major consideration All of it has held up better than aluminium TV masting.

Instead of the white or tan PVC plumbing pipe, use the gray PVC electrical conduit. It is the same sizes, but is usually rated for outdoor use. Read the printing on the pipe. (Also less visible.)

Plastic I broke off and sanded down from old wall warts.
Plastic from milk bottles.
Plastic from Soda bottles.
PVC
Leather boot laces
The leather from old shoes or boots.
The rubber left over from old shoes or boots
Rubber from truck tire tubes (also act like shock cords)
Bungee cords.
Heavy duty rubber bands (FREE FROM THR MAIL CARRIER)
Plastic coat hangers.
The plastic from old Floppie disk
Clear plastic tubing.
Surgical Tubing
Sling shot tubing stretch several feet and also will absorb the wind load.
Medicine bottles.
The list is endless.

Considering that PVC plumbing needs to be able to survive boiling water
that melted PVC is a surprise. It must get really hot in AZ.

PVC, the white stuff is not rated for Hot Water. CPVC the beige stuff is. White PVC will melt in the direct sun (Dallas TX) and freeze and become very brittle in the winter (Pepperell Mass). CPVC will become even more brittle in the winter than PVC will (also Mass). Both are lessons personally learned. I don't know about the grey stuff, NMET (Non Metallic Electrical Tubing) as I have not tried that.

Considering that PVC plumbing needs to be able to survive boiling water
that melted PVC is a surprise. It must get really hot in AZ.

Thank you!!

I live in Michigan. My son, who lived in Phoenix, made a luggage rack
out
of PVC pipe and it melted all over the top of his Jeep.

But in Michigan, it could last a bit longer.

Oh OK,
You guys are speaking of the antenna support.
Check your local airport that does repairs.
Also contact some hang glider clubs.
They use 60-61-T6 aircraft tubing.
The one I had I used two 20 foot sections and sleeved them together and
guyed them 1/2 way up.
I moved to Poway,CA in 1980 then came back East and it's still there after
28 years and just 7 blocks off the ocean front,it tolerated all those storms.

I worked in both commercial and domestic HVAC and also with my Dads plumbing business
I lost count of the number of homes we had to tear out PVC that was piped into the hot water
110* is about the limit if you care to use it.
140* and it's going to melt
There are three types of plastic in general use. Black plastic, which is ABS,(Acylonitrile Butadine Styrene) and white plastic which is PVC and CPVC,(Polyvinyl Chloride and Chlornated Polyvinyl Chloride) ABS is used for drainage. PVC is used outside the house for cold water feed from the pump or the meter.
PVC is banned in many States for home use except for cold water.
Prepped right and the use of the proper glue the joints will hold and you may get away with the thick walled PVC
The reason for the PVC was because someone said the solder joints in copper contain lead and it can leach into the water.
Well they also banned R-12 refrigerant and converted over to R-134-A but they never told public Joe that R-409 was just as good as R12 and has the same pressures and cools as well as R-12
Sorry for drifting off the topic but I saw what EPA did and it hurt many people and forced us to pay thousands for recovery machines.
Now 134 causes global warming so I think Europe is starting to phase that out
Go with a metal mast

OK- Supports:...I think I've mentioned these before, but the local paint dept of Lowes has extendable pain poles. They are at least partially fiberglass,maybe all. Telescopic locking sections in varied sizes. I provided a link to see some:
http://www.lowes.com/lowes/lkn?action=productList&N=0&Ntk=i_products&Ntt=paint%20poles
I think 16 feet extended was max, but on a field day with them secured in a weighted umbrella stand, and a few nylon guy lines, you're up and running.

I just looked at the 40 foot super pole priced at $250.00
How high of a mast do you want?
So far the bast I seen is the one on ebay
Two 28 foot poles just under $80.00 with shipping fees
The shipping is the same for one 28 foot pole so you can buy 2 and sell one

https://www.jackite.com/index.php?cPath=41

the jackite telescoping pole is more of a field day thing. I picked up one and was quite supprised that fully extended it did carry a fair amount of weight. Duck tapeing the coax to the mast kept everything in line and prevented the the mast from flexing to much. all of the reviews on EHAM.net are 5's. I figured since that was the case why not try one.

I am not sure if you would need 3 or 4 or more poles to support a dipole with a balun. Perhaps someone out there has tried this.

I would email the company and ask how they handles AZ heat or NY snow. But there is a Kite shop near Bodega ca (Hour or so N. of SF on the ocean) that leaves their telescoping poles up all year long so UV should not be a problem.

If you are referring to 300 Ohm TV Twin Lead, absolutely. Many great antennas were built with it. I ran it at 100 Watts on a dipole into an MFJ-949E tuner with great results. It is getting a bit hard to find as everyone has gone to 72 Ohm coax (RG-6).

That sounds like 300 ohm twin lead with a small balanced output tuner you could make a double zepp antanna and use it on mulipule bands. Using balanced feed line your dipole only needs to be 1/4 wave on the lowest band you intend to operate. I have a 150' dipole up feed with 450 ladder line and I can tune most of 160 meters with it.

Just curious by what you ment by this statement. "I think you'll notice very different noise characteristics between
your wire and the vertical as well."

Are verticles more noisy?

---- Chris <kingsqueak@...> wrote:

==========
A LOT of the reviews on eham for the zerofive are astroturfing IMO.
The claims are just not possible for what the antenna is. I was very
curious about that antenna and did some modeling in MMANA and when you
wide band tune a vertical that is long for the band, the radiation
angle is horrible.

Also, the conditions right now are horrible to test a vertical, the
bands have hardly been open lately.

I run a GAP Titan (also a big compromise antenna) in addition to wire
antennas and when the band is open, depending upon conditions it can
be a real winner. It all depends on how the propagation is working
though.

I think you'll notice very different noise characteristics between
your wire and the vertical as well.

The vertical shines with the more distant contacts, the bands just
haven't really been open for that lately.

The last plumbing code I worked with limited PVC water pipe to 150 degrees F and something like 125 PSI water pressure. I was on several commitees looking at plastic pipe and thought "listing" or approving water pipe under those conditions was kind of dumb when the basic protection for a water system is the pressure and temperature relief valve on the water heater that is set for 150 PSI and 200 degrees. Kind of like using wiring that blows before the fuses. Also PVC used for cooling water in our plants soon failed from vibration when connected to pumps or other machinery.

Now, kite shops sell kite and streamer masts that are made of some kind of reinforced plastic, black in color and we have had one in the yard for several years and it shows no sign of problems with a fairly long (ten feet) streamer blowing in the Southern Calif desert winds and sun.

Final update...

OK Zero-Five 43 footer is working UFB now...

some Idiot (and I am not going to name names...) installed the ground rod strap to the Positive terminal of the Balun.

Well, thats fixed now and She radiates nicely now. I will continue to install a few more Radials, after work today and on Monday, to try to get the Nrs up to 60 Radials...

Right now w/32 Radials the GP workes as good as my 55' high Cobra Dipole (dB RX wise) ... so no need for elevated radials, even though I read an interesting article yesterday ... stating they mixed a grounding system (part elevated, part on ground) w/ good results. I might try to run 3 elevated 132' Radials for 160m.
Using Dacron tie-off at 16' hight...one can angle the radials right off the radial plate at apprx. 45 deg. upward and install the elevated radials out at 16' hight. This should get me a better Topband match and performance.

Well, anyway...
Thanks again to a great people of this Forum for all the help and suggestions.
Steve, W1CDX

4981. Moxon for 20 M fed with 450 ohm?

Yahoo group: ham-antennas (2008)
Date: 2008-05-25 22:54:29 UTC
From: Bruce Conner
Topic: 4981 Message: 4981

I have a moderately long run (60-100 feet depending) to an area where I'd like to set up a vertical Moxon antenna for 20 meters. I know they are normally driven with 50 ohm coax, but I'd like to cut the losses for my qrp work by using 450 ohm window line as the feeder. What sort of 9:1 balun (transformer, actually, since both sides should be balanced in this case) should I make? I've got some 114-43 cores and about 50 watts max. Can I get away with that?

I figure the transformer/balun is my easiest solution, but maybe somebody knows how to fiddle the dimensions of the antenna itself to be driven directly with higher impedance line? Suggestions please?

For getting Adobe to work again, you can try a system restore to just before the "update".
Also try reinstalling said update or waiting for another update.
I have had to do that with a few things in the past, especially under Windows XP.

Gentlemen: I recently switched from Adobe to a free downloadable program called Foxit PDF - found it first
thing on Google and it is many many times faster than Adobe reader plus you have the ability to manipulate
the file. I immediately dumped Adobe that I had used for years - FWIW to you Dave / N?ATH

It depends on what you are using for control cable. I used Rotor Cable (overkill, I know, but it was what I had on hand) and just laid it on the ground with the Coax. Never had a problem.

I would conduit the coax unless you have "Hardline".. Direct bury coax does not mean it's "waterproof".

Direct bury means that the coax will not leach anything bad into the soil.

Use conduit, and make sure that you don't get water into it. Proper drip loops in the conduit is a must.

You'll be glad you did.

AE5MH

That's a thought, although the mechanics of it could be a challenge.
The delta would have to come off the side somehow and be supported.
It's worth considering, however.

4989. Mosley Mini 33A Advice Please

Yahoo group: ham-antennas (2008)
Date: 2008-05-28 18:40:58 UTC
From: wc0l
Topic: 4989 Message: 4989

I have a Mini 33A and would welcome any advice on the best way to tune it. Using the factory default settings, it seems to resonate around the top end of 20 meters. I can move the radiating element traps out to hopefully bring the resonate frequency down some, hopefully to around 14.2 mHz. If I do that, should I move out the traps on the director and reflector an equal amount? Has anyone ever fine tuned the director and reflector as per the manual instructions?

Any other ideas for improvement? Has anyone ever removed the director and just made it a two element beam?

The way this antenna is now, it definitely radiates a signal, but acts more like a dipole than a beam. Any thoughts are appreciated.

Thanks and 73,
Mike, WC0L

4990. Re: [ham-antennas] Mosley Mini 33A Advice Please

Hello Mike - I would think you would only want to move the
outer element ends, not the trap covers - otherwise it would seem
that you would be moving the resonance on 15 as well as 20 - I once
had a 33 that I (during field day) got the reflector / director spacing's
reversed and the pattern went bananas - figured it out, reversed the
settings and it had a very nice pattern for a small beam- I was actually
pleasantly surprised it worked as well as it did - It just seems to me that
the element trap covers would be the end of the radiating element for
each higher band. Hope this helps / Dave / N?ATH 73 & Gud Luk

4991. Telephone Cable Stealth antenna

Yahoo group: ham-antennas (2008)
Date: 2008-05-29 00:44:59 UTC
From: Jonathan Helis KB5IAV
Topic: 4991 Message: 4991

I've got an idea for a stealth antenna and want to know if anyone else has tried this.

In the bedroom we've converted to a radio room, there was a telephone line that was added after the house was built. We removed the phone jack when the room was repainted since it didn't work and we didn't need a phone in there anyway. The telephone cable, around 50 feet or so of it, is still on the outside of the house running from near the room to the opposite side of the house.

Since I have an LDG Z-11 Pro autotuner and a LDG 4:1 balun that I got free with the tuner, I was consdering trying this out as an antenna. I just wonder how telephone cable will work as an antenna. It isn't connected to the phone box anymore so that won't be an issue.

I've used end fed antennas in the past with good results and thought maybe I should give them a try again, since the wire is already there and I have other supplies I need.

This will be a stealth antenna, since I live on a small lot in close quarters. I also won't be running more than 100 watts since I don't have an amp and usually run my TS-140S at about half that anyway.

Just curious.

>The telephone cable,

Hello Jonathan,

First no I haven't tried it for transmitting. Several questions though. You already found out its not connected. Good. Now is it 4 wire, 6 wire or something else? Solid or stranded. Stranded probably won't take 100 watts. Are you thinking tieing the lines together? That might create harmonics. Is the line near the ground or high by the gutters? Near ground it would probably act like a nvis antenna. Good for local work. High near metal you might have an issue with the wire reacting to the gutters. (I have limited space and they really affect my verticle antenna). Is the wire close to the electrical outlets? Might pickup noise. I would try receive first and see what happens. Then start with low power with a local net or friend and work from there. Hope some of that helps....

Hi Mike,

I hope someone has a direct answer for you. Just my thoughts. If you have trailer hitch a screwdriver antenna from High Sierra I have heard is good. They also sell a claw clamp that attaches to just about anything (side rail for example) for a hamstick style antenna. That you can adjust right to the frequency you want. It would be cheap and easy to remove for parking garage and/or security. Hope that helps some.

Hamsticks are the cheap way to go and they work good too. All you need is a 3/8 X 24 mount, coax and your good to go. Make sure to ground, and then ground some more...I've used one for 75 meters on a dodge van and it does surprisingly well...Good luck, Alan

Jon;
My radio club (when I lived in Western Michigan), had two telephone cable anttenas. One cut for 40 and one cut 80, that we used on FD. They were made out the thick black wire and were somewhat stiff. Don't know if that is what you have, but they worked very well for us. (I borrowed both of them once for SS, and ran them in an inverted vee with supports over my roof; neighbor came over and asked if I was tieing my house down!)

4999. Which Antennas to purchase?

Yahoo group: ham-antennas (2008)
Date: 2008-05-29 06:18:27 UTC
From: mblaise@nycap.rr.com
Topic: 4999 Message: 4999

Right now I have a IC-706MKIIG with 50Ft. of Belden 9913 connected to the Diamond X510N 2M/440 Omni and the LDG AT-7000 auto tuner / 25ft RG-8U / G5RV at 30ft above ground in a slightly inverted V formation.

I am looking for a 2M beam for both FM (distant repeaters) and SSB use, a 440 beam to reach distant 440 repeaters, a 6M beam for DX and a 40M / 20M / 10M for DX.

The only problem is that I can only put up a tripod mount at my QTH. My XYL doesn't want anymore antennas on our apartment and neither does the landlord. I already have the G5RV, X510N and a scanner antenna.

I was thinking about purchasing a heavy duty 5ft. Easy-Up tripod mount and a section of 10 ft mast and a good rotor and installing these 4 beams on the peak of my roof:

1) Cushcraft A4S 4 element 10/15/20M with the 40M add on kit. This would be on the bottom of the mast at 40 lbs.
2) Cushcraft A505S 5 element 6M beam. This would be next above the A4S at 11lbs.
3) Cushcraft 719B 19 element 440MHz beam. This would be above the A505S at 6lbs.
4) Cushcraft A14820T - 2M -10H/10V (10 horizontal and 10 vertical beams for both FM and SSB work). This would be on top at 7lbs.

As far as economy and space go this is the best I could come up with. I would have to run 5 lengths of coax. Do you guys think the tripod will hold all of these beams (64lbs)? Would 10ft. of mast be enough? Do you think this setup will work OK?

Any suggestions on other antennas or comments would be greatly appreciated.

Thanks,
Mike

Antennas 101 - Anything will radiate.
The question is - how efficiently.
Next question is how much power it will accept from your transmitter.
If you can match this piece of wire to your transmitter you will have it made.
Next question ☐ if you care ☐ where it will send its radiated energy?
I would venture to speculate it will be absorbed by your house walls and very little of it will get to wandering around the globe.
As they say in Business 101 ☐ you get what you pay for.
I am just curious as you are and would like to know how is the 60Hz reception when you shorten both ends of the wire ☐ use it as an end single wire ☐ and how is it when used as a single end fed pair of wires.
In theory the 60Hz and other noises should cancel in ONE twisted pair.
Of course again assuming that you have a single twisted pair telephone cable running around your house.

Using real scientific approach ☐ I would run an SWR analyzer on it!

Just an opinion Mike - I think it will be pretty iffey - if you are in a low lying area - If the roof is not to high so as to catch a lot of wind - if you are very careful an lucky during assembly - If you could do most of your assembly from a step ladder - I guess I am suggesting that most of the tripods I have seen in this area are pretty light weight - Not knowing where you are or the characteristics of your mast and tripod I would think you are loading it to an extreme, at least for the ones I have seen - Glen Martin Engineering in Booneville MO. I think has some heavier built ones I think, You might check the specs on line on his as they have some very nice products - I think your selection of antennas is fine just questioning the strength of the mast and tripod, vs. where your antennas might be located at.

Would a severly loaded 80 mtr ham stick be better than the same mount with a standard 9 foot steel whip with an antenna tuner? The latter would have heigth as well as more capture area,no?

Hamsticks are the cheap way to go and they work good too. All you need is a 3/8 X 24 mount, coax and your good to go. Make sure to ground, and then ground some more...I've used one for 75 meters on a dodge van and it does surprisingly well...Good luck, Alan

5005. A Couple HF Dipole Questions

Yahoo group: ham-antennas (2008)
Date: 2008-05-30 02:45:33 UTC
From: Ronald Smith, Jr.
Topic: 5005 Message: 5005

I want to put up my first dipole, but I only have about 70 ft of space to hang it and the dipole would only be up about 25 ft. I would like to run 40, 20, 15, and 10.

I was told I should get an Alpha Delta DX-EE for starting out.
But I came across the New Carolina Windom by Len Carlson K4IWL
<http://www.hamuniverse.com/k4iwlnewwindom.html>

I'd like to try building my own dipole.
I would like something I can easily rebuild / repair without a lot of expense. I get ice and wind storms in my area that cause tree damage a couple times a year. So I'm thinking the dipole I put up, will break at least once a year. Unless there are tricks for putting up a dipole to have them survive ice and wind storms.

Is a New Carolina Windom dipole a good choice for a beginner or is Alpha Delta DX-EE a better choice? Or is there something else better for limited hanging space that I can build?

Are all baluns the same? Is a 4:1 balun for $70, better then a 4:1 balun for $35? And is worth spending the extra money?

Thank for the input.
Ron N2MSV

5006. RE: [ham-antennas] A Couple HF Dipole Questions

Yahoo group: ham-antennas (2008)

From: James Fogg
Topic: 5005 Message: 5006

For storm survival, place a spring at each end of the wire, and support the feed point with a mast. Some guys use pulleys at one or both ends and weighted buckets, but a lot of evidence shows this encourages breakage because it starts whipping the wire as the buckets fall. Don't pull your wire too tight, a little sag will help with water runoff to reduce ice and it also reduces tension to improve ice weight survival.

Even at 40M, a height of 25 feet is going to give you a high angle of radiation, so you'll get great local coverage to about 700 miles, but you might not get good skip. At higher frequencies 25 feet will begin to perform at a lower radiation angle.

If you are building/repairing I recommend a dipole for performance and simplicity. At 40M the length is about 66 feet.

Many wire antennas are directional (toward the sides), but you can hang a dipole as an inverted V and get a good omni-directional pattern.

For multi-band no-tuner performance you can build a dipole as a fan dipole. You start with a dipole for your lowest (longest) frequency and then add additional parallel radials cut to length for each band. Since electricity is lazy it will always choose the path of least resistance, which is the resonant radiator.

There is a wealth of free online info about dipoles and fan dipoles. Buy a 1:1 balun (about $25 US) and some wire (insulated solid copper14ga "house wire" works great) and start building.

Oops, sorry. The height above ground / angle of radiation note is mostly about dipoles. Some other wire designs aren't as sensitive to elevation. This is both a curse and a blessing about dipoles, as you can dial your angle of radiation with elevation. But if you are limited in height you might not get the angle you want. At 80M 40 feet is about as low as you want to go unless NVIS is desired.

Ron,

You might want to take a look at a Cobra Ultralite Junior. I have the Senior model which includes 160m and I am very pleased with it and I am not much higher then you. You might end up with the ends dangling a little bit but that should be fine.

Jim, K6JMG

Thanks Dave. So it sounds like the Tripod might not hold that weight.

Any other suggestions?

---- N0ATH <n0ath@...> wrote:

Just an opinion Mike - I think it will be pretty iffey - if you are in a low lying area - If the roof is not to high so as to catch a lot of wind - if you are very careful an lucky during assembly - If you could do most of your assembly from a step ladder - I guess I am suggesting that most of the tripods I have seen in this area are pretty light weight - Not knowing where you are or the characteristics of your mast and tripod I would think you are loading it to an extreme, at least for the ones I have seen - Glen Martin Engineering in Booneville MO. I think has some heavier built ones I think, You might check the specs on line on his as they have some very nice products - I think your selection of antennas is fine just questioning the strength of the mast and tripod, vs. where your antennas might be located at.

Subject: [ham-antennas] Which Antennas to purchase?

Right now I have a IC-706MKIIG with 50Ft. of Belden 9913 connected to the Diamond X510N 2M/440 Omni and the
LDG AT-7000 auto tuner / 25ft RG-8U / G5RV at 30ft above ground in a slightly inverted V formation.

I am looking for a 2M beam for both FM (distant repeaters) and SSB use, a 440 beam to reach distant 440
repeaters, a 6M beam for DX and a 40M / 20M / 10M for DX.

The only problem is that I can only put up a tripod mount at my QTH. My XYL doesn't want anymore antennas on
our apartment and neither does the landlord. I already have the G5RV, X510N and a scanner antenna.

I was thinking about purchasing a heavy duty 5ft. Easy-Up tripod mount and a section of 10 ft mast and a good
rotor and installing these 4 beams on the peak of my roof:

1) Cushcraft A4S 4 element 10/15/20M with the 40M add on kit. This would be on the bottom of the mast at 40
lbs.
2) Cushcraft A505S 5 element 6M beam. This would be next above the A4S at 11lbs.

3) Cushcraft 719B 19 element 440MHz beam. This would be above the A505S at 6lbs.
4) Cushcraft A14820T - 2M -10H/10V (10 horizontal and 10 vertical beams for both FM and SSB work). This
would be on top at 7lbs.

As far as economy and space go this is the best I could come up with. I would have to run 5 lengths of coax.
Do you guys think the tripod will hold all of these beams (64lbs)? Would 10ft. of mast be enough? Do you
think this setup will work OK?

Any suggestions on other antennas or comments would be greatly appreciated.

Thanks,
Mike

The great thing about dipoles are that they are cheap- if you do it homebrew. You might want to do an inverted Vee- I had limited space and did an inverted Vee and it's fine. Try doing it yourself first. Also you can let the ends of a dipole go down vertically if the space is too small.

my .02 cents worth
Joe

Remember when you buy an antenna like you are talking about you are paying someone else a big price for a little bit of metal you can make yourself. A 5 band beam is a different animal for a first antenna. A dipole type is good to start with I have made most of them at one time or another. The easiest is a fan dipole as James Fogg noted in his email. Mine is 75, 40,20,17 &10. All run on one coal line. You might not have room for 75 but no problem with the other bands. When you need to go higher check out a mast for the center , I have a 40 ft tilt up mast for mine, all home made. The 5 band dipole held up through the bad ice storms we had here in the Midwest last year. I lost many big trees as did a lot of people around here but no problem with the antenna.

I like to thank you all for your input.
It sounds like I'm better off building my own dipole.
And as couple of you noted the fan dipole is easiest to start with
so I think I'll start there.
Is it possible to build a fan dipole in an inverted V shape?
I like the place a spring at each end of the wire idea.
I'm going to look into a mast for the center, maybe I can get more
height.
James Fogg mention a 1:1 balun for about $25 US.
Are all 1:1 baluns the same?
There is a Hamfest locally in New Jersey this weekend (Saturday). I
like to go and pick up a 1:1 balun there. But what do I look for in
a good balun?

Hi Ron, First off I want to second those who approve of the homebrew approach. Nothing is more satisfying than when something you made yourself does the job well for you. Also, nothing can be more frustrating than when something you made yourself is giving you trouble. ;-) The antenna I decided on a couple of months ago is an off-center-fed dipole, close relative of the windom. I built mine as a 1/2 wavelength on 80m, gives me six bands under 1.5:1 without a tuner. Would be a little long for your QTH though. The June issue of QST has plans for one right up your alley, though. It's a 1/2 wave on 40m. Requires making a balun for the feedpoint, and will probably involve experimenting with different length/feedpoint location combinations. That's the frustrating part. Using it now that it's dialed in, that's the satisfying part. I built the A-frame mast in the ARRL antenna book which gets the feedpoint up about 35ft. There's lots of better setups out there, but this is a nice place to start. Good luck, and above all, have some fun!

5015. Re: [ham-antennas] Mosley Mini 33A Advice Please

Yahoo group: ham-antennas (2008)
Date: 2008-05-30 18:45:29 UTC
From: Wayne
Topic: 4989 Message: 5015

While the antenna looks to not have the best front to back ratio, it should still do better than a dipole.
Not seeing the exact setup, I would want to move the outer elements out for a bit lower resonant frequency on 20 meters.
You don't mention where it shows on 10 and 15 meters.
I would remeasure the lengths carefully, and compare to what the instructions say.
Changing any part can affect the whole, and needs to be checked and rechecked on each band. Anyway, the overall length of the elements is for the lowest band, in this case being 20 meters.
There is bound to be a good amount of compromise on a physically small antenna for these bands.
heck, I have an old Hy Gain 6 meter beam, 4 elements, and it is huge compared with some. Has a 12 foot boom, and does very well, or at least it did till I took it down for moving.

I feel that if you move the traps out, you will affect all bands, not just 20 meters.
So try moving the outer ends out as much as p[ossible first.
And yes, you should also move the reflector elements out at well.
Difficult to test on the ground, though can be done to some extent, supported on wood.
Beg, borrow or buy an analyzer. Can save a lot of guessing, and easy to check best resonance on each band.
YMMV

Hi Bill,
An off-center-fed dipole, close relative of the windom that sounds a
little easier to build than the fan dipole, for my first try at
building a dipole. I'll look at that the June issue
of QST for the 1/2 wave on 40m. I'll have to get my hands on the
ARRL antenna book and read up on an A-frame mast. I was afraid of
the homebrew approach for my first dipole due the frustrating
factor. Until joining this user group asking questions
and getting good answers from people with different points of view
on how to get started.

5017. RE: [ham-antennas] Re: A Couple HF Dipole Questions

Yahoo group: ham-antennas (2008)
Date: 2008-05-30 21:01:58 UTC
From: James Fogg
Topic: 5005 Message: 5017

All 1:1 baluns are similar. Some can handle more power, but any of them should handle 200W. Look for one that appears to be able to take the stress of the wire antenna hanging from it. I like ones that have a mounting eye bolt at the top so I can hang it from a support.

There are also 4:1 baluns which are used to convert ladder line feeds to coax, and aren't appropriate unless you are using ladder line.

Yes, fan dipoles can be built as inverted V's. For any inverted V you'll need sufficient height to allow a V angle of 45 to 120 degrees (unfortunately I slept through trigonometry, but there are some trig websites that'll help you figure out how high you have to get to achieve your angle). It's also a good idea to have enough height at the center so that the ends don't come closer than 10 feet to the ground to prevent someone from getting an RF bite should they touch it when you transmit. Mine come within 4 feet, but I live in the back woods of New Hampshire and if anyone is in my yard they have bigger problems than a silly antenna.

Not all wire antennas will perform well as an inverted V. You'll need to check design plans for other types of home built wire antennas. You should also know that if you choose to use ladder line as a feed, or if your antenna design requires ladder line (some do, the ladder becomes a radiator at certain frequencies), then the ladder line needs to be kept in the air and away from anything metal, or other antennas and feedlines. Some antenna designs require that the ladder line remain near vertical.

When you are looking at wire antennas remember that each design is intended to address specific needs (multi-band, shortened, positioning problems, disguise, etc.). It's not unusual for a non-dipole wire antenna to have some trade-off that you have to live with (performance, radiation angle, etc.). Google is your friend.

I like to thank you all for your input.
It sounds like I'm better off building my own dipole.
And as couple of you noted the fan dipole is easiest to start with
so I think I'll start there.
Is it possible to build a fan dipole in an inverted V shape?

I like the place a spring at each end of the wire idea.
I'm going to look into a mast for the center, maybe I can get more height.
James Fogg mention a 1:1 balun for about $25 US.
Are all 1:1 baluns the same?
There is a Hamfest locally in New Jersey this weekend (Saturday). I like to go and pick up a 1:1 balun there. But what do I look for in a good balun?

5018. Which vertical???

Yahoo group: ham-antennas (2008)
Date: 2008-05-30 21:57:54 UTC
From: Rob Thomson
Topic: 5018 Message: 5018

Dear Group

I have the opportunity to install a plain tubular vertical and was considering a quarter wave for 40m. However, I do love 30m and 20m !

Given that the pole is actually primarily to be used to support a long-wire, I need to keep it high. I could introduce some base loading...

What are your thoughts and recommendations?

A fan is a easy way to start, a dipole works if the center droops a little or if it supported a in the center becoming a inverted "V" . A inverted V will give a better SWR than a straight dipole with normal 50 ohm coax.

If you want information on a easy to make center support look at my tilt over setup in the photo section. If you are interested I can email you a drawing and construction information.

From: John P.
Topic: 5005 Message: 5021

My 2 cents follows.....

Most important is to keep it simple and not over build at first.

Remember that to buy some antenna system is paying them to measure and cut wore for you.

I have here 2 fan dipoles - #1 for 75, 40 & 20 (works of 15 also) with a broadside East-West
#2 for 20 & 15 with a broadside North-South

The f1rst dipole's center is at about 45 feet and the other dipole's center is at about 38 feet and directly below the first one and of course oriented 90 degrees.

I do not see any noticeable interaction.

Center insulators are made from short lengths of 2 1/2 PVC with eyebolts for a) each side of the dipole, b) support rope on top, c) support rope for coax.
I used a "clean out" plug on the top so that I can get inside for maintenance. At the bottom I mounted an SO-239. They both work well.

As far as supports, if you have trees use them. If you do not have a tree for the center try to span a rope between 2 trees to support the center and one other tree at each end for the ends. If you need a support pole, consider using a piece of Oak Stair railing. These come in 20 foot sections and I am told that they can be had for $1.50 per foot. You make it a tilt over, but the support would cost only $30.00 each!

As far as spacers, I used 9 inch lengths of 1 inch diameter PVC. This gives a 4 inch separation between fan dipole elements. At the ends I also used a piece of this PVC.

If you use a tree - IMPORTANT - do not forget to put a retrieval line so that if the antenna breaks you can pull down the insulator. Otherwise you may be STUCK!

As far a design if the "center support rope span" idea above does not work, consider a rope with the antenna supported below it (at several points) in a catenary fashion (like the overhead electrified rail road). My second dipole has this configuration and I have a double rope (smaller size) with one side passed thru a loop in the main rope to apply tension and assist in obtaining the correct "profile" or "droop" on the antenna.

As far as wire, I use #12 stranded & insulated wire here. The insulation is of the "THHN" type and I came across an article that stated that this insulation will reduce the "velocity factor" by about 4 %. Thus the calculated length will be 4% shorter.

As far as cutting to length what I have found that works best is to cut it 5% to 7% short. Then at each end I PERMANENTLY attach a tuning stub drooping down. This stub will usually be enough to make the total 102% which for 20 & 15 is only about 1 1/5 foot. You can twist it gently back on itself to "tweak" the resonance of the antenna.

Also, I found that it works best to start with the lowest frequency (e.g. 75 meter legs) and work up to the highest. Also I tune each one individually. That is I connect ONLY the one being tested/tuned. After that I connect ALL and "tweak" as needed.

As far as rope, there a many great ideas out there, but I got 5/8 inch nylon for 5 cents per foot at a surplus store locally. Of course, I use this for the main supports only.

If you go to http://www.ac6v.com/ you will find tons of useful information.

I feed the antennas separately with RG-8x and the SWR is mostly 1.5: or below.

I do not use a Balun at all at this time. I might use a Balloon to put up a long wire if I get a large weather Balloon and some Helium however! (Hi Hi)

As I said, however, keep it simple and experiment. It is one of the fun things about Ham Radio

I like to thank you all for your input.
It sounds like I'm better off building my own dipole.
And as couple of you noted the fan dipole is easiest to start with
so I think I'll start there.
Is it possible to build a fan dipole in an inverted V shape?
I like the place a spring at each end of the wire idea.
I'm going to look into a mast for the center, maybe I can get more
height.
James Fogg mention a 1:1 balun for about $25 US.
Are all 1:1 baluns the same?
There is a Hamfest locally in New Jersey this weekend (Saturday). I
like to go and pick up a 1:1 balun there. But what do I look for in
a good balun?

From: John P.
Topic: 5005 Message: 5022

In my previous post I forgot to note how I got the rope 60 feet up in the trees....

I used a 25 pound bow and a simple target arrow (Walmart) & 25-pound-test fishing line.

After shooting the line, I used it to pull up mason line. I then used the mason line to pull up small rope. Finally, I used the small rope to pull up the large rope.

I did find out that taping (electrical tape) the connections between the increasing sizes of rope enabled the rope to be more easily pulled over the tree branches.

Of course you could always use a remote control model helicopter to carry the line aloft over the tree, hire a crane, of some other rediculous method!

73's

"John P." <jpetrocxme@...> wrote:
My 2 cents follows.....

Most important is to keep it simple and not over build at first.

Remember that to buy some antenna system is paying them to measure and cut wore for you.

I have here 2 fan dipoles - #1 for 75, 40 & 20 (works of 15 also) with a broadside East-West
#2 for 20 & 15 with a broadside North-South

The f1rst dipole's center is at about 45 feet and the other dipole's center is at about 38 feet and directly below the first one and of course oriented 90 degrees.

I do not see any noticeable interaction.

Center insulators are made from short lengths of 2 1/2 PVC with eyebolts for a) each side of the dipole, b) support rope on top, c) support rope for coax.
I used a "clean out" plug on the top so that I can get inside for maintenance. At the bottom I mounted an SO-239. They both work well.

As far as supports, if you have trees use them. If you do not have a tree for the center try to span a rope between 2 trees to support the center and one other tree at each end for the ends. If you need a support pole, consider using a piece of Oak Stair railing. These come in 20 foot sections and I am told that they can be had for $1.50 per foot. You make it a tilt over, but the support would cost only $30.00 each!

As far as spacers, I used 9 inch lengths of 1 inch diameter PVC. This gives a 4 inch separation between fan dipole elements. At the ends I also used a piece of this PVC.

Just some info.
An ebay seller is selling two 28 foot foot fiberglass telescopic poles
$64.99+ $17.40 shipping for both poles
They telescope down to 48"
Pour down a small concrete and insert # 80 PVC to insert the mast.
Then you can take the antenna down in less then a minute during storms or
for working on it

Jim,

Why not buy a REAL helicopter - just in case!!!

Of course, you could always use a .22 rifle and tie the fish line to the bullet and shoot it over the tree

5027. RE: [ham-antennas] Re: A Couple HF Dipole Questions

Yahoo group: ham-antennas (2008)
Date: 2008-05-31 02:38:07 UTC
From: James Fogg
Topic: 5005 Message: 5027

Since you sound like you are new to radio, I should mention why we use a balun with a dipole.

A dipole has an approximate feedpoint impedance of 50 ohms when used at the frequency it was cut to length for. If you feed it with 50 ohm coax and your radio is designed for a 50 ohm antenna (nearly all are, and anything modern definitely is), then everything is fine. Except, you'll find RF current on your feedline shield, and that can cause problems, including RF bites at your radio. A 1:1 balun isolates the feedline (at RF anyways) and keeps all the RF current in the antenna.

A 4:1 balun matches a 50 ohm radio/coax with antennas and feedlines that aren't 50 ohm, such as 400 ohm ladder line or 300 ohm television "twin lead". Also, ladder line is a balanced feedline. Neither conductor is at ground potential. Coax is unbalanced, since the shield is grounded. This is actually a simplification, but will work for now.

Some people skip the 1:1 balun for a dipole and instead wrap a few turns of the coax around a little piece of PVC pipe at the antenna. This will work to isolate the feedline at RF.

Subject: RE: [ham-antennas] Re: A Couple HF Dipole Questions

All 1:1 baluns are similar. Some can handle more power, but any of them should handle 200W. Look for one that appears to be able to take the stress of the wire antenna hanging from it. I like ones that have a mounting eye bolt at the top so I can hang it from a support.

I hope you see now that there are no hard and fast rules to getting an antenna up or how to support the ends. Higher is better but some people will argue about each ½ or ¼ wave increment in height for each band. Most of us use what we have be it tree or pole. I do know the more you do your self the more fun it becomes. All my very successful attempts and failures have been done as per □SWAG□***. This method will always work in the long run.

SWAG *** scientific wild ass guess

Defintely recommend the Hustler verticals. I tested the 5-BTV for three months and it worked very well, especially on 20m and 40m. 80m is very narrow indeed.

The 6-BTV would cover 30m. Not sure about using it to support a long wire though!

I use a slingshot with a closed face spinning reel and 15lb line, I use a .5 to .75 oz sinker I fire it up and over the branch and then use it to raise a messenger line and use that to hoist the heaving line. The system will get my lines into the tallest pines on my property so I am quite happy with it. I can get up to about 85 feet or so with a bit of work. I am quite happy with this method if the XYL helps I can have both ends of an antenna up in about half and hour.

Topic: 4993 Message: 5037

A few deatils with hamsticks, being as I have a 6 meter version, and read the instructions for all models.
First, I suggest buying Stainless Steel allen set screws. the 6 meter came with ones that take a regular screwdriver, and the slots get messed up easily.
Second, check SWR at two points to see what you may need to trim off the "stinger" (steel whip part), and be sure to _NOT_ shove it down inside, as they made them with a part of the winding going through the center of the hollow portion of the whip. At least that is what the instruction sheet says. You don't want to risk cutting that wire. The six meter version did not have the wire going through the center though.

I bought a set of IronHorse whips, similar to the Hamsticks. Those can be tuned without cutting the stinger. May actually be a bit broader banded due to capactitance. They seem to have discontinued these however, except for one or two versions.
Even these could stand having the set screws replaced with Stainless Steel, as the originals get a bit rusty, and deform in the allen portion too easily.
One place you may be able to get the Stainless versions is Ace hardware.

Note, most of these types of whips may need retuning if moved to another vehicle.
And as stated, a good ground at the mount works best.

RG58, and Mini 8 (8x) is normally adequate for up to 150-200 watts.
I prefer soldered connectors to crimp, and seal the coax at the antenna end to keep moisture of all sorts out.

Due to the height of these antennas, I suggest using a heavy stainless steel spring at the base.
Plated springs will eventually rust. And you want some "give" in case you conatct a tree branch, wire or ???...
any possible mounts. You can roll your own in some instances.
I used a heavy 4 magnet base with spring and a set of bayonet mounts.
Mine are Also from Iron Horse, also no longer available it seems.
As a set, I got one stud and 5 top sections. Note, different makes made theirs slightly different, and not always interchangeable. With mine, it allowed for a fast band change. had to stop to do so, but worked reasoably well.
I contacted Sweden, Finland and Russia on 20 meters from north of Seattle in washington, Seattle to California on 40 meters, and even Oregon to California on 75 meters.
100 watts on a 706 MK II G.
Vehicle was a Saturn wagon, antenna in middle of roof...
YMMV

If your state allows "wrist rocket" style sling shots they work really well. Someone makes something called the EZ Hang (http://www.ezhang.com), which is a wrist rocket and a fishing reel. It's expensive ($100). I made the same thing for $25.00 in new parts from Wal-Mart. If you have a reel or sling shot you are already ahead of the game.

If you want to "lift" them into place you might want to look at a Jackkite pole, they work great. Anytime I have to place anything with a degree of precision I use my Jackkite pole. I think the max length is 32" but that amounts to almost fifty with a step ladder and the average man. Best part is the collapse to about 4' log.

Theory is one thing, practice another
If you get the antenna itself to radiate enough, it can work very well.
But I tend to wonder about antennas that require a tuner for al
frequencies in use.

In an actual test, I seemed to get better results from a 75 meter dipole than from a 150 foot (or more) random end fed wire. the end fed was/is an old type telco wire, and I used both parts tied together at the tuner. Worked, but nowhere near as well as the dipole. Might have worked better if I had shortened it to 1/4 wave on the lowest band I tried it on (160 meters).
A reasonably good RF ground can help a lot.
YMMV

A 75 meter ham stick would be far better than using a 9 foot stell whip
and a tuner.
For a 9 foot steel whip to come even close, you'd need a big loading coil
at the base of the whip.
The Hamstick, and similar antennas, use a helically wound wire on a
fiberglas form, and a small steel whip for adjustment. Once properly
tuned, it will be electrically 1/4 wave at the frequency adjusted for.
The common 9 foot, usually shorter, steel whip was cut mainly for 11
meters. Shorten a bit for ten meters.
Actually, the formula comes out that a 9 foot steel whip would more
likely be resonany at about 26 MHz, and would need to be trimmed to work
properly on 11 meters.
Using a tuner to get a plain 9 foot whip to work on 75 meters would mean
that much power would be lost in the tuner. And some tuners could not
handle it.

The "latter" as you call it, would not really have "more" capture area.
Back to antenna basics 101...
And for the record, I used a 75 meter Iron Horse whip, similar to the
Hamstick, and had fairly good results with it.
YMMV

If you build your own dipole, all you need is wire, #16 stranded or even 14 or 12 better, some insulators (you can make these out of PVC or similar material) and coaxial cable.
A balun is not 100% essential.
the dipole I put up in 2002 had no balun at first. I added a 1:1 W2AU balun afterwards, and saw no real difference in performance.
You can form a balun of sorts by using a coil of coax at the dipoles feed point.
You will see many arguments pro and con about using baluns.
You will see many arguments saying to use ladder line to feed the antenna.
I will simply say that a plain center fed dipole, resonant on the lowest band you plan to use, will do as well as all the other types, and be a lot less expensive to make.
You can often get hunks of wire free that will work as well.
My present antenna is a double dipole, 75 meters and 160 meters. the 75 meter part is #12 insulated wire, and does well enough. the 160 meter legs are mainly #16 stranded wire, also works well, and with a tuner, also works well on 40 and up to 10 meters. Would work on 6, but my present tuner won't work for 6 meters. I have talked around the world using simple dipoles. main thing is to get the wire up there and tuned...
A basic 40 meter dipole is only about 64 1/2 feet long (32 1/4 feet each leg).
I always start a bit long and adjust downward as needed. Allow a bit to wrap at the insulators.
I have used both steel guy wire and heavy cords to support the ends. I set mine up so I can drop the center as needed, using a pulley and cable to support the balun.
I have heard stations in the caribean on 160 meters (I am in West Texas)
And some time back, I talked to St Thomas, virgin islands, on 40 meters from near Modesto California early in the morning. Of course, it depends on time and band conditions.
YMMV

The W2AU Balun is rated for 2000 watts, so no real problem there, especially at $24.95 or whatever. I have been using mine since 2002 and no problems whatsoever with it.
The W2AU balun does have the eye for supporting it.
I had bought mine at HRO, but they don't list it in their catalog now.
Maybe AES or one of many other places out there...

5047. Avanti Astro Plane for 10m?

Yahoo group: ham-antennas (2008)
Date: 2008-06-02 02:29:46 UTC
From: ve9xyz
Topic: 5047 Message: 5047

I found my like-new disassembled Avanti Astroplane in the basement recently and just happened to see its description in an old 1969 Allie Electrinics catalogue: "SWR less than 1:1.4 on all CB channels and 10-meter ham band."

Mine is exactly like the one featured in http://www.rigpix.com/antennas/avanti_av101.htm I remembered that its gain was reportedly 4.46 dBi and I wonder if this is in fact a good antenna to resurrect for my Kenwood TS-570DG.

It was an odd looking thing, but worked well as I recall. I'd have thought that I'd need to trim it but I'd not be certain where to start.

With slight length changes, this will be an excellent antenna for 10 meter operation. The only thing that will be better would be a beam.

5049. Homebrew 20 meter vertical

Yahoo group: ham-antennas (2008)
Date: 2008-06-02 12:29:09 UTC
From: Sean Doran
Topic: 5049 Message: 5049

Had a blast making a vertical this weekend for 20 meters (8-12 radials for now). It was quite educational comparing it to my Windom. The patterns seem different and one antenna performs better than the other at various times, so clearly the lobes are different. Only time will tell as to whether one is consistently better than the other.

You would want to trim the two vertical sides to make shorter.
It depends on how old it is and how the tubing is swaged.
If the two top halves aren't swaged at the bottom where they join you
can trim there.
If they are swaged and made larger for the bottom sections to fit
into then trim them at the top where they fit into the mounting
bracket.

From: James Fogg
Topic: 5049 Message: 5052

That's the thing with HF antennas, there's no perfect winner. Each design has something attractive about it (even a poor performing compromise antenna might be attractive because of space requirements). VHF and above tends to erase the differences. With significantly smaller construction allowing more complex designs, little effort to bounce skip (though some do) and mountain top repeaters it gets easier.

5053. Matching 75ohm to 50ohm

Yahoo group: ham-antennas (2008)
Date: 2008-06-03 11:41:04 UTC
From: Rob Thomson
Topic: 5053 Message: 5053

Dear Group

I have searched the archives but found no suggestions on this one...
does anyone have any ideas for matching 75ohm coax to the 50ohm
connection on the transceiver?

As I work in the cable industry, I have a plentiful supply of low-loss
75ohm coax and am using it to feed various dipoles (inherently 75-ohm
impedence in any case). I don't seem to be able to find any
instructions for a suitable "un-un" (other than single frequency stubs).

Any suggestions welcome.

Regards
Rob, G4LMW

Any suggestions welcome.

5054. Re: [ham-antennas] Matching 75ohm to 50ohm

Yahoo group: ham-antennas (2008)

From: Andy
Topic: 5053 Message: 5054

If your entire antenna system is 75 ohms (all cables, and whatever is on the end), you could just live with the mismatch. The SWR between 75 and 50 ohms is only 1.5:1, which isn't bad at all.

An "antenna tuner" at the rig could be used to null out the difference. Some automatic antenna tuners, however, stop adjusting once the SWR reaches 1.5:1.

There are wideband (resistive) matching devices that correctly match the two impedances, for people in instrumentation who need precision matching, but with several dB's of loss which is much worse than the loss due to a 1.5:1 SWR.

I guess you could wind an auto-transformer. There are some commercially made 50/75 ohm transformers out there (http://www.comm-connect.com/sp8004.htm being one for low power).

Andy

Keith's message sounded experienced. Any idea about how broad this
thing is uncut, and then, if that isn't great for amateur bands,
does anybody know how much I shorten the vertical sides?

Thanks guys

It would be good on 10 meters, with a bit of trimming, or 12 meters using a tuner.
With a good tuner, you might not need to trim it. I forget the exact construction detail, but with a bit of effort could be figured out. Would be great if you could find the original intructions for it.
I'd check the SWR at the ends of the portion of ten meters that you are allowed to operate, and work from there.
It is most likely equivalent in gain to a vertical dipole.
They used a lot of hype when coming up with gain factors.
YMMV

From: ke4vyn
Topic: 5062 Message: 5062

Ok guys, a friend asked me about putting up a vertical, "why the need for tuned radials?"
His thoughts are just a long (i.e. 130 foot) counterpoise, insulated to replace 'tuned' radials.

The antenna is a DX-88 and will be mounted 4 feet high.

I know what I said, but what is the groups thoughts?

Thanks all,

Mike, I think the mystry is solved!!!!!
While looking thru one of my "prized" archived copies of "Ham Radio" from 1978
I saw an advertisement for a CrushCraft new vertical called ATV-5.
Then searched the Web and found other pictures and data...I will post in the photo section
for others to investigate.
73 Ken
Interesting Search!!!!!

Greetings all,

I just posted 5 photos in the 'Name That Antenna' folder. This antenna
was discovered by a friend of mine and thus far, neither of us have
been able to ID it. I told him I'd post it here in hopes that someone
would recognize it.

Thanks for the assist.

5066. 20 meter Vertical

Yahoo group: ham-antennas (2008)
Date: 2008-06-04 19:51:37 UTC
From: brad gass
Topic: 5066 Message: 5066

Because of room constraints and the way a dipole will radiate on my property, I want to use a Vertical mono band 20 meter vertical antenna. Anyone familiar with a commercialy built 20 meter vertical antenna on the market? (must be able to be used on PSK SSB)

N3JPL

5067. Re: [ham-antennas] Re: Avanti Astro Plane for 10m?

Yahoo group: ham-antennas (2008)
Date: 2008-06-04 19:53:03 UTC
From: Wayne
Topic: 5047 Message: 5067

As I said, I would check the SWR first, on a couple fo frequencies, to get an idea. If it is, say 1.9:1 at 28.5 and 1.75:1 at 28.300, this tells you it need to be shorter.
I'd tend to try about 1/2" off the bottom two parts, and maybe 1/2" off the top section.
For the record, that "X" at the top is a capacity hat, which does two things. It electrically lengthens the top, and also makes it broader banded.
I know the basic construction on the antenna, just not the details on how it is assembled and fed.
You want to aim for the lowest SWR at the middle of the portion of ten meters than you want to operate. But each time you trim, recheck the SWR at both ends and in the middle.
As I say, try maybe 1/2" thje first time, and second time maybe 1/4", depending on how it turns out. Easier to remove a bit more than to add.
I have an old 11 meter antenna, either 1/2 wave or 5/8, possibly 3/4 wave, that will be easy once I redo it, and it will be a matter of simply sliding the sections togeter to make them shorter.
I have no real idea as to how borad banded the Astro plane really is.
Could tell with my analyzer though...
YMMV

5068. Re: [ham-antennas] 20 meter Vertical

Yahoo group: ham-antennas (2008)
Date: 2008-06-04 20:04:30 UTC
From: Sean Doran
Topic: 5066 Message: 5068

I just built one and it works VERY well. I purchased two 1 1/2" x 10 foot PVC pipes and pieced them together (PVC cement). I then ran 17 feet of wire through some stand-offs up along the side, painted it all brown, and dropped about 8 radials. Because of the color, my wife has yet to notice it. :)

I've been using it on 20m for roughly a week and love it. It has been performing better than my Windom. AND, it performs better with less noise. I am a believer in verticals. I am hearing Hawaii and Germany on 20 in the evenings and that has been during the low sun spot activity from northern Michigan.

Thank you Sean, but like most advanced HAM's we have all read the literary. As this amounted to what I told my friend.

BUT, as we all know what in theory does not necessary make up the same events in practice.

So, I guess I should have asked if anyone has tried this.

Thanks for the link as I am sure someone has never seen it.

My experience is that the more radials the better and if they are elevated, tune them and then 2-4 of them is sufficient.

My 20m vertical

I went to the Bass Pro shop and bought a 20ft fiberglass telescoping crappie rod. Remover the top real small section. Installed a small wooden dowel in the top hole to stiffen things. I then put two pieces of 1☐ EMT together for the bottom, a 1☐ wood dowel in the top of the EMT and put the fishing pole on the top of the dowel. I used some epoxy to glue it together, left spacing in the dowel for my coax. Ran 14 ga wire 16 ½ ft up the fiberglass rod , put epoxy on the joints . Used 4 wires for the lower. This set up get the center feed above 16 ft so the lower wires cab be spread for a better 50 ohm match.

From: David Lewis
Topic: 5062 Message: 5076

Hi Lee,
If you're friend mounts the vertical 4 feet above ground,He may
run into problems,with the antenna trying to couple with the
ground,and tuning properly.Most antenna makers call for no more than
about 10 inches,for ground mounted antennas.
73,David

Hi,
I would like to see the details of this 20m vertical also please,
maybe you could load the photo's in the group photo folder as others
may be interested also, if not please cc me a copy.
Thanks
Nigel ZL2SEA

Gents,

I'll be sure to send out some photos of my vertical in about 4-5 days.

Maybe I can post them?

Stay tuned... no pun intended.

Subject: Re: Quest for information

John,
Many Thanks for the confirmation of the ATV-5
I will pass this information on to the party that was searching for the ID.
Myself ,I at this time have no need of the Manual, but glad to find out that it is available.
My Thanks again,your response is appreciated!

Subject: RE: Quest for information

It is indeed an ATV5
I found the Instruction Manual for it, actually covers the ATV3, 4 and 5.
Send me $5 cash if you want me to make you a copy.
Don?t ask me for parts on this antenna. There are none available, unless you can find common hardware with other antennas ? which is quite likely... but the traps and coils, etc. you are on your own.

Subject: Quest for information

A group of us have been searching for the answer of the I D of this antenna.
I think it is a Cushcraft ATV-5 from the years of l978 or later.
Would you have any archives that would have more information about this antenna,
If you can shed any light , I would appreciate it

5080. Cushcraft MA5B mod

Yahoo group: ham-antennas (2008)
Date: 2008-06-05 22:26:52 UTC
From: ldelmarter
Topic: 5080 Message: 5080

Has anyone tried adding more elements to the Cushcraft MA5B beam? I'm wondering if a director for 20-15-10 could be added by extending the boom a few feet. Maybe the boom and reflector (adjusted to director length) from another MA5B could be used. Of course, it wouldn't pay to buy another new beam just to rob parts from but may a used or junk beam could be used to make a full 3-element 20-15-10 antenna. Possibly a director for 17-12 could also be added to the new boom section. Does anyone have any thoughts on this?

Les, WB6YIK

5083. 5btv

Yahoo group: ham-antennas (2008)
Date: 2008-06-06 00:51:16 UTC
From: wb4mnk
Topic: 5083 Message: 5083

I have a 5BTV vertical which has a 80 or 75 meter resonator but I have know idea which one it is because the Hustler resonators are marked 75 or 80 meters and the coil is covered in white heat shrink.

The resonator I have is covered in black heat shrink and the only thing that is on the heat shrink is a white dot at one end. I am not sure if the white dot means nothing, is the bottom or maybe the top.

I guess it could be an after market resonator.

Wonder if anyone might know what this resonator is or have any information that could help me find out what it is?

73,
Art

5084. Inverted-V question

Yahoo group: ham-antennas (2008)
Date: 2008-06-06 09:41:29 UTC
From: lecontejoe
Topic: 5084 Message: 5084

I recall reading something about the inverted-V being directional ????

Am building a new house and after examining every possibility, it looks as though an inverted-V is the best I can do. I'll probably take my current trap dipole -- cut for 40 with traps for 20 and 15 -- and install it as a V.

Is the inv-V directional, or, is it directional only with a narrow V angle?

Thanks.

5085. RE: [ham-antennas] Inverted-V question

Yahoo group: ham-antennas (2008)
Date: 2008-06-06 11:48:42 UTC
From: James Fogg
Topic: 5084 Message: 5085

My understanding is that an inverted V is considered to be omni-directional, or nearly so. I recently converted my 80m dipole to an inverted V and found it behaves like an omni-directional antenna, but I haven't operated enough to be sure how much so.

I also found that as an inverted V there seemed to be a bit more noise, such as a vertical would have. I've found lots of references to this on the intarwebtubes.

My goal in the conversion wasn't space (I have lots of that), it was to gain the omni-directional behavior.

From: Brian Hall
Topic: 5084 Message: 5087

A half-wave dipole is broadside directional (figure 8 radiation pattern) when installed as a flat-top. As the ends are drooped, directivity is decreased approximating an omnidirectional pattern when the ends are drooped 30degrees or more. The standard inverted-vee configuration provides a nearly omnidirectional radiation pattern.

5088. CRAIGSLIST-search all craigslists in the world at ONE time! Here's how, please pass it on!

Yahoo group: ham-antennas (2008)
Date: 2008-06-07 00:20:39 UTC
From: Vlincoln
Topic: 5088 Message: 5088

Craigslist is almost larger than EBAY, and a lot less expensive!

A large number of folks do not know how to search more than one or a couple of craigs list sites at the same time.

I have found (in surfing the internet), the instructions on how to search the whole USA craigslist at one time. (or any part of it.)

OK, here goes the secret:

1. Bring up the google search box, that all of us normally use to search using google.

2. type into the box:
site: craigslist.org and the item your wanting to find.

3. press enter.

that's it.

for example

in the google search box, type site:craigslist.org akai m-8

it'll search ALL craigslist sites, for the akai m-8 machine, and give you all the urls for each machine.

COOL?

also, for searching, a string to search with is entered like: "tape recorder"

and if you do not want to find (for instance cassettes) type -cassettes,

and if you want to search specific states type them like
this michigan OR minnesota OR utah OR wisconsin
and wal la, away you go.

COOL?

van lincoln

5090. Re: [ham-antennas] Re: Inverted-V question

Yahoo group: ham-antennas (2008)
Date: 2008-06-07 02:54:56 UTC
From: Ruben Echevarria
Topic: 5084 Message: 5090

Let's put it this way... I live in a 3 story building.
I have access to the roof by way of the building owner.
I put the antenna up as best as I could without causing holes or
damage. It's on a 10 foot mast (apex) it extends 51 feet or so to
one corner of the building and another 51 into the backyard where
there is a pole ... It's attached to the top of the pole.
I didn't pull out my tape measure to adjust anything I just set it up
per the instruction sheet and left it alone. If I need to tune it I use
an MFJ989C tuner. This is life in the big city. Under the radar.
As long as it works and I'm on the air I'm not going to get technical.
No I didn't trim anything. Just used the instruction sheet.

Let's put it this way... I live in a 3 story building.
I have access to the roof by way of the building owner.
I put the antenna up as best as I could without causing holes or
damage. It's on a 10 foot mast (apex) it extends 51 feet or so to
one corner of the building and another 51 into the backyard where
there is a pole ... It's attached to the top of the pole.
I didn't pull out my tape measure to adjust anything I just set it up
per the instruction sheet and left it alone. If I need to tune it I use
an MFJ989C tuner. This is life in the big city. Under the radar.
As long as it works and I'm on the air I'm not going to get technical.
No I didn't trim anything. Just used the instruction sheet.

What is the height of the antenna's center point?? How high off the
ground are the ends?? Did you have to trim the antenna wires to get
it resonant??

Thanks.

5095. RE: [ham-antennas] Matching 75ohm to 50ohm

Yahoo group: ham-antennas (2008)
Date: 2008-06-08 02:22:58 UTC
From: W5TA
Topic: 5053 Message: 5095

Rob,

There are many solutions to this problem. Probably the one I've received that I like best is: ignore it. True, most all modern transcievers are "looking" for a 50 ohms load, but most will still put out full power into a 1.5 to 1 (or 2:1) SWR, and the loss, especially on the lower HF bands is essentially negligible.

Among other schemes is using a half wave length of coax, that only works for monoband antennas. The ARRL book on baluns also treats "un-un's". And, you can always use an internal or external transmatch. They make automatic ones now, if you want to avoid twisting knobs.

Google it, and you'll find plenty of suggestions.

GL OM,
Dick W5TA

Subject: [ham-antennas] Matching 75ohm to 50ohm

Dear Group

I have searched the archives but found no suggestions on this one... does anyone have any ideas for matching 75ohm coax to the 50ohm connection on the transceiver?

As I work in the cable industry, I have a plentiful supply of low-loss 75ohm coax and am using it to feed various dipoles (inherently 75-ohm impedence in any case). I don't seem to be able to find any instructions for a suitable "un-un" (other than single frequency stubs).

Any suggestions welcome.

Regards
Rob, G4LMW

Any suggestions welcome.

From: ve9xyz
Topic: 4934 Message: 5096

I have this same antenna and did a lot of research here and elsewhere until I could figure out what it was too.

The same chap at Cushcraft helped me with the manual which was well worth the $5 since there's good info in it about tuning lengths and radial lengths that would have taken a lot of time to figure out by trial and error.

I've had frustrating weekends trying to get good connections at the trap (screws into aluminium mast) and keeping water out of the traps, but this thing tunes up on all 5 bands (80, 40, 20, 15 and 10). Such is the fate with newer units too, I suspect.

If you need some measurements I took good records (somewhere).

It is indeed an ATV5
I found the Instruction Manual for it, actually covers the ATV3, 4 and 5.
Send me $5 cash if you want me to make you a copy.
Don?t ask me for parts on this antenna. There
are none available, unless you can find common hardware with other
antennas ? which is quite likely... but the traps and coils, etc. you
are on your own.

Hi James,

That's a good article on shunt-feeding a pole that already exists. However, when your site doesn't have anything resembling a mast, you have to bring your own. Some years ago, I built a 40' tilt-up, rotatable mast that supports a Cushcraft A3 (3 element 20/15/10m yagi). A single person can erect it but two or more bodies makes it go faster… typically, two or three hours.

The mast is made using commonly-available 1¼" Schedule 40 pipe (~1.66" OD), rigid conduit couplings, 1½" floor flanges that work as rotating guy collars on top of the couplings, and an X-shaped base made from 1”x1” angle iron. There are two guy sets -- midpoint and near the top. The mast sections are 5’ – 10’ – 10’ – 10’ – 5’, so the top guy set is 5’ down from the top. The support for the midpoint guy set is a coupling that is welded to the middle 10’ section after turning the threads out on a lathe. A 1½” coupling could be used w/o having to do any lathe work. The couplings are pinned thru one side of the sections using small fine-thread bolts w/ threads cut in the couplings. I can see (now) that it could be done w/o welding.

The top guy set performs double duty as inverted vees for 80m & 40m. The 80m antenna is a 4-wire cage, covering about 400KHz of the band w/o a tuner. Since the 40m inverted vee is only a single wire, it's made using 1/16" stainless steel wire rope. The three antennas are fed from separate feedlines with choke baluns.

There's a tee at the bottom of the mast that allows a 20' cantilever boom to be used during lifting/lowering. The cantilever boom is screwed into the “branch” side of the tee. The bottom end of the tee has a close nipple screwed into it, which is passed thru a flange that’s bolted to the base unit. A cap underneath the tee “captures” the mast.

For lifting, two lengths of wire rope connect to the mast just below the midpoint and top guy collars and connect to the free end of the cantilever boom. A winch provides the muscle for lifting & lowering. My original winch was a manual worm-drive boat winch fixed to one end of a rectangular steel frame, with the winch positioned just a touch more than 20' from the base of the mast. I parked one of my pickup truck's front wheels over the other end of the winch base. I now use an electric winch on the front of my truck.

The midpoint guys & 40m inverted vee antenna that are 90° to the direction of the mast are laid out and then tied off to anchors that are inline with the bottom of the mast. The

anchors consist of 3' long 3/4" steel rods driven into the ground at an angle pointing toward the mast. The top and midpoint backstay guys/inverted vee are also anchored, with their overall length calculated using simple geometry. The cantilever boom is held upright during lifting/lowering using temporary rope guys, tied to the midpoint anchor stakes on either side of the mast. Once the mast is tilted up, the forestay guys/inverted vees are tied to their respective anchor stakes, and the other guys/inverted vee lengths are adjusted so the mast is more-or-less vertical. The cantilever boom can then be removed. The lifting wire ropes are taped to the mast until needed for lowering. I use a short piece of 1¼" pipe and a stake to prevent the mast from being rotated more than 360° (and subsequent winding of the feedlines around the mast).

At this point, the operating tent is set up, next to the mast. The last time (in 2007), a new operator was dubious about the safety, so he setup his tent away from the mast. Prior to last year, we used my friend's tent trailer, parked right next to the mast. With the trailer positioned such that the zipper for the screen window (at the operating position) was parallel to the mast, we were able to reach thru the zipper opening to rotate the mast. A piece of tape w/ N-S-E-W markings on it makes it easy to tell which way the antenna is pointed (very handy at night). A plethora of still photos are here: http://www.geocities.com/bswadener/fd2007/ and http://www.geocities.com/bswadener/fd2003/

On the 2007 page, there's a 30 second video clip of the mast being lowered (the last thumbnail image). Catch me in FD2008, operating 2E-WWA!

73,
Bryan WA7PRC

I made a 2m slimjim from http://www.hamuniverse.com/ke4nu450slimjim.html

first question) Why do we connect the coax shielding to the short side? I would think that by connecting the shielding to the antenna it would also radiate radio frequencies.

second question) is it normal to connect the coax shielding to the antenna?

When I hooked up the antenna to an antenna analyser. If I used a short coax to feed the antenna the SWR fluctuated wildly especially if the antenna moved. However with a long coax the SWR was always 1:1

Question 3) why would the swr fluctuate if the antenna moves? from my extra test: the electrical charge important to radio is conducted on the exterior surface of the wire. The antenna surface area remains constant.

> would also radiate radio frequencies.

Some say a J-pole works better with the coax shield on one side or the other of the 'J' matching section. Others say it doesn't make much difference.

The truth is (I think) that neither is truly ideal, because neither side is RF neutral so there will be some current along the outside of the coax, unless you add a choke (current balun) to decouple the coax from the antenna. Perhaps just a few coils of the coax near the connection point. But many hams use antennas without such chokes or baluns, so it may work well enough without one.

> second question) is it normal to connect the coax shielding to the
> antenna?

Absolutely. The coax shield has to go somewhere, because both leads have currents and a voltage between them. Even for a ground plane antenna, whatever constitutes the 'ground' plane is a part of the antenna and needs to be connected to the coax feedline. At VHF the shield must connect to some part of the antenna.

> When I hooked up the antenna to an antenna analyser. If I used a short
> coax to feed the antenna the SWR fluctuated wildly especially if the
> antenna moved. However with a long coax the SWR was always 1:1

Hmm, if the longer coax is long enough and lossy enough (RG-58 or (gasp) RG-174), it will behave like a dummy load and you'll measure a nice low SWR no matter what you put on the other end. Nice SWR, but not much of your TX power is making it to the antenna!

Do you see a low SWR even if you disconnect the coax at the antenna end?

> Question 3) why would the swr fluctuate if the antenna moves?

I can think of two possibilities:

1. Any antenna is affected by its environment. If it is near ground, or metallic objects, or people, they will affect its SWR.

2. If you have a common-mode problem (or "current-on-the-outside-of-the-coax" problem), touching or moving things near the coax will affect the SWR. In fact that is one way to tell that you have such a problem.

Andy

The SlimJim is a J-Pole antenna made from ladder line. If properly built and installed it should have low SWR over the entire 2 meter band and then some.

The fact that the SWR changes violently when the antenna moves could mean mean two things:

First you may have a cold solder joint somewhere. Try screwing the coax pigtail into your antenna analyzer and wiggling the cable immediately behind the PL-259 connector. If the SWR swings from flat to infinity and back you need to resolder the connector. Are your solder joints bright and shiny or crinkled and dull? I have no idea what power soldering iron you used, but it is virtually impossible to get a good solder joint on a PL-259 with a 15 or 30 Watt soldering pencil. Find someone who has a 150 Watt or bigger soldering GUN (the 100W job Radio Shack sells isn't big enough either). Work fast and apply heat to the connector not directly to the solder. Let the work melt the solder and flow into the joint until you have a bright shiny connection.

Second, if using the short piece causes the SWR to fluctuate it could be you are simply too close to the antenna and your body capacity is detuning it.

73 and good luck,

My problem is probably all of the below. I had found a coleman battery soldering iron around. figured it was a weekend project so I used that. If I liked making antenni and other electrical work then buy a good iron.

as for the lenght of the coax. the short was about 6in. The long was probably 30ft.

In the other email responses. I had not thought about metal things around my antenna, but my slim jim was laying across a steel vice for most of the SWR readings. I was also moving the antenna with my hands, saying to myself "Ok there is constant metal surface area, I have insulated everything. I wonder why the swr is not constant"

Well first antenna made. It was fun and easy.

I have made 4 different "Slim Jims". They are all very susceptible to detuning if any thing is close by so the short coax can be a problem. The lower part should be at least a quarter wave above a metal mount. Over all there has been good performance reports from the people that I have made then for. I hang mine out in the open and support then with a monofilament line during building and testing, I have made three with 450 ohm that was purchased and one for me that I made my own 450 line with 14ga copper weld. It has a wider spacing and was mounted on larger PVC conduit. Keep all conductors away from it and the SWR should not change.

I made mine and slipped it into a PVC pipe with a cap on each end. Bottom cap I drilled a hole to accomodate an so239 female chassis conection so I could attach my coax cable. I made the PCV about 8 inches longer so I could place it on a mast with clamps and the j-pole was above the metal. This 10 ft mast goes into a patio type umbrella stand for field day use.

The average J Pole is fed in a compromise feed.
Designs that feed the end of one of the two elements directly, with the other element being grounded to the base and mast, are less likely to have these problems.
I built two J Poles, one for the 1 1/4 meter band, and the other a dual band, based on the design as Arrow Antennas uses. The length of the feed line makes little difference, other that the losses in said feedline.
An antenna made of flexible wire, like twinlead, will show some variations in movement, especially with shorter lengths of coax. The antenna was meant as a fast portable antenna, not really as a base antenna.
People often take a basic design and modify it, maybe seeing some improvement depending on how they feed it and how it was constructed.
Mine have always shown a good match no matter where I mounted them, or how long the feedline was.

The J Pole design has been around for a long time now.
It is a 1/2 wave antenna with a 1/4 wave matching stub.
Also known as a vertical end fed zepp...
The types like I have could be mounted horizontally, which would be good for SSB, CW and a few other modes. At frequencies lower than 144 MHz, the design starts getting bigger so is not as easy to implement. OTOH, a horizontal dipole is a bit easier to handle, and in theory, both designs should have the same gain.
The differences are due to variables, such as:
How and where the antenna is mounted.
How the antenna is fed.
Loss in the feedline (and there will be some).
Objects between the antenna and the station/repeater being worked. Big metal buildings will attenuate the signal a great deal. Where I was living, there was a large milk plant between my location and many I wanted to work. This also affected the TV reception.

In order to fairly test an antenna against another, both must be tested under the exact same conditions.
the same mounting location.
The same coax or equivalent, including length of same.
the same radios at both ends.
And a few more I don't recall just now.

Note that two different makes and models of radios will have some differences in reception, and so on...
YMMV

Phil , did you come up with any numbers or percentages for dimensions when you put it in the PVC. I have always found the SWR to change inside of PVC. Inside would look nicer inside then tie wrapped to the outside like mine.

From: Joe - wb6agr
Topic: 5112 Message: 5112

Hi. I am looking at trying the MFJ 80m end fed Zepp, The antenna comes with 100 feet of feed line. This is somewhat long for my installation, anyone have any idea what the results would be if I shortened the Feed line to 50 or 60 feet ?

The result - you may send it to me, I could use it in FD.
Just kidding.
I am assuming it is a twin lead ladder line already "notorious" for low loss.
Cutting it in half will sure improve feed line loss by half, but you may never notice it.
BTW ☐ how long (in wavelength) is your Zepp?
If everything goes according to plan I am going to put up phased array of two extended double Zepps on 40 meters on FD. I am very curious to test the actual radiating pattern.
On paper it looks ☐awesome☐ - over 12 dbi ☐gain☐. Pretty sharp for 40 meters, maybe too sharp Hi Hi.
Anyway ☐ cut away with gusto!

Hi Ham Antenna Group,

I am new to the group and a new general. Please see a diagram of my inverted V to loop conversion and my antenna system at:

http://ph.groups.yahoo.com/group/ham-antennas/photos/view/f4ef?b=1

http://ph.groups.yahoo.com/group/ham-antennas/photos/view/f4ef?b=2

Best DX contact so far has been ZL3SV(New Zealand) on 75 meters.
ZL3SV uses a 1500' center fed sloper.

May cycle 24 be kind to you.

Cheers.

From: cjmagnetman
Topic: 5115 Message: 5116

With the recent talk about the 450 ohm J-pole.
I was thinking about placing one inside a fiberglass pole that i use
as a walking stick and connecting it to a bnc and using a 5 foot piece
of coax to connect with a handi when i needed somthing more than a
rubber duck. I was thinking of using the ARRL dualband out of 300 ohm
that is in the files section of this group. I was planning on using
foam to take up the slop between the pole and the ladderline to keep
it from banging around and some kind of loop to hang over a tree limb
when i needed to use it. Does anybody have any thoughts on this project?
Thanks
KE4KOX Chris.

I can't say for sure: but you may like to check out the information on Dr. Ace's site
73 Ken

Dr.Aces WH2T Antenna InfoWith this antenna the feed line should be routed away from the antenna at a right angle for as great a distance as

possible. This will prevent current imbalance in the feed line caused by RF pickup from the antenna. A right-angle

departure of 1/4 wavelength or greater is suggested.

To avoid problems matching any center fed antenna with high impedance open wire lines, keep the feedline around

these lengths.

[The WORST POSSIBLE line lengths are shown in brackets]

160 meter antenna 35-60, 170-195 or 210-235 feet
[Avoid 130, 260 ft]

80 meter antenna 34-40, 90-102 or 160-172 feet
[Avoid 66, 135, 190 ft]

40 meter antenna 42-52, 73-83, 112-123 or 145-155 feet
[Avoid 32, 64, 96, 128 ft]

Some slight trimming or adding of feedline may be necessary to accommodate the higher frequency bands.

I currently use a 75 Meter Full Wave Delta Loop on the 6 thru 75 Meter bands with a tuner. I am very pleased with

it! I also currently use a 160 Meter 1/4 wave inverted L antenna.It will tune 6 thru 160 meter bands!

Subject: [ham-antennas] 80m Zepp

Hi. I am looking at trying the MFJ 80m end fed Zepp, The antenna
comes with 100 feet of feed line. This is somewhat long for my
installation, anyone have any idea what the results would be if I
shortened the Feed line to 50 or 60 feet ?

Routing a feed line away from the antenna at right angle is OK.
Trimming the feedline for stated reasons is a ham radio urban myth and should be propagated as such especially to new hams.

I made it per instructions, and slipped in the pipe with no problems. Seems to be wide band enough. A good little project, not rocket science. I would consider putting it on a permanent mast. Doesn't seem to be critical in construction if instructions followed. I like mine. If anyone is anal, one could slip it in the PVC tube and check SWR during building. I didn't,and was fine, velocity factors be damned!

Phil , did you come up with any numbers or percentages for dimensions when you put it in the PVC. I have always found the SWR to change inside of PVC. Inside would look nicer inside then tie wrapped to the outside like mine.

I made mine and slipped it into a PVC pipe with a cap on each end. Bottom cap I drilled a hole to accomodate an so239 female chassis conection so I could attach my coax cable. I made the PCV about 8 inches longer so I could place it on a mast with clamps and the j-pole was above the metal. This 10 ft mast goes into a patio type umbrella stand for field day use.

I have made 4 different "Slim Jims". They are all very susceptible to detuning if any thing is close by so the short coax can be a problem. The lower part should be at least a quarter wave above a metal mount. Over all there has been good performance reports from the people that I have made then for. I hang mine out in the open and support then with a monofilament line during building and testing, I have made three with 450 ohm that was purchased and one for me that I made my own 450 line with 14ga copper weld. It has a wider spacing and was mounted on larger PVC conduit. Keep all conductors away from it and the SWR should not change.

Until you are talking about open wire or window line at 450 Ohm or so, then the length of the transmission line can be manipulated as a matching stub.

A Zepp fed with coax, often uses window line as a matching stub and the length is critical based on the single band the Zepp is cut for. It brings a match for 5/8 wl each leg dipole to coax at ~50 Ohm for the given band. We're not talking about a plain dipole cut to resonance with 1/4 wl legs.

An end fed Zepp fed with window line direct from a tuner can also have issues depending on the transmission line length due to the transmission line radiating if it is cut to the wrong resonant length.

It all depends on the context.

Sometimes weird things happen and an antenna that doesn't work needs to be modified. I have had to do it with doublets and other antennas that use open wire, as well as coax. I first make sure the feedline is not missmeasured then work from there. Sometimes you will find a change in the velocity factor of the openwire, some are only 80% and are listed over 90%, other times you will find other things detuning the antenna conductive dirt is one. Cleaning and waxing the line can have a real effect on open wire antennas that don't like to tune. Me I am going to build a 3 band beam for HF and run and reversable wire beam NS and EW for 40 and 80 so back to making insulators out of Plexiglass.

From: vaclav sal
Topic: 5123 Message: 5125

Never "worked" 6 meters and would like to try in next Field Day.
Are there much activities on this "TV" band during Field Day?

Not counting plain dipole - what is the basic and simple 6 meter antenna to homebrew?
Does polarization matter? Would vertical double extended Zepp hanging from a big Texas oak tree do?

When your analyer shows a different factor from the published one, it does effect the electrical length. 99% of the time the length doesn't need to be changed, but when an antenna cut and built to the published info from several sources doen't work as in the thing wont load, there has to be a problem, be it coax or ladder line. I have a doublet, 102 feet in length feed with a length of ladder line 45 feet, it should load, it would fine according to the charts, but the velocity factor is closer to 80% instead of 95% that is a 15% difference which makes it see almost a half wave at 40 and a quater wave at 80 which does cause interactions. I agree most of the time, the feedline is the last thing you should fool with, just like the carb on a car, but sometimes it is needed not often. It isn't a total urban legend, you just need to confirm and adjust some time, the theory to the real world, velocity factors do matter.

Hi,

visit www.cebik.com you will need to register online,
no cost to do so, then you can access a wealth of antenna info.

Take a look at the Moxon for 6 meters

http://www.cebik.com/content/a10/moxon/6m.html

I built one with # 12 thhn copper wire, direct fed
with 50 ohm coax, no matching needed, works great,
built a second using 1/2" aluminum tubing.

Listen for W4DW 7A on 6M and all bands all modes.

Topic: 5053 Message: 5133

Rob, a dipole erected horizontally is actually supposed to be 75 ohms. It's when you begin to invert-vee the dipole that it comes closer to 50 ohms,as I understand. I'm no expert, but when one is using a radiator for more than one frequency the impedence varies all over, if I remember correctly...
Do I have this right,folks?
I wouldn't sweat it.

Subject: [ham-antennas] Matching 75ohm to 50ohm

Dear Group

I have searched the archives but found no suggestions on this one...
does anyone have any ideas for matching 75ohm coax to the 50ohm
connection on the transceiver?

As I work in the cable industry, I have a plentiful supply of low-loss
75ohm coax and am using it to feed various dipoles (inherently 75-ohm
impedence in any case). I don't seem to be able to find any
instructions for a suitable "un-un" (other than single frequency stubs).

Any suggestions welcome.

Regards
Rob, G4LMW

Any suggestions welcome.

Electrically no difference. Practically, mount the elements on top. The boom will help support them,whereas mounting them underneath you are completely dependent on the nuts/bolts attaching them to the boom. It's just good practice. I also used to spray my assembled antennas with a good clear polyurethane arosol that was made for antennas,but any good outdoor type will do.This seals the aluminum from corrosion, and helps keep connections, hardware,etc protected from salts,acid rain, electrolysis, etc. (don't spray threaded connections intended for coax PL259's until after assembly.)

When constructing (my case reassboling), should the elements be mounted on top of the boom or the bottom? Or does it make a diff?

Phil has some good points. I would like to add another small one. Where you can, always install the bolts with the nuts on top. this way if you loose one you can see a clear hole. With the nuts all on the lower side , if vibration is a problem you wont know until the last one fails. When I was working and we built fatigue testing assemblies this was some thing we always did. Also you cant do a partial assembly , put something together and forget the nuts if they are on top.

5139. Bird Model 43 problem

Yahoo group: ham-antennas (2008)
Date: 2008-06-22 21:50:47 UTC
From: lecontejoe
Topic: 5139 Message: 5139

This question may not be completely on-topic for this group but this is the only place I know to go for help.

My Bird Model 43 is driving me nuts -- it won't work reliably.

First, the history. I purchased my Bird in the mid-1990's, used it regularly for a few years, then packed it away and stored it while I moved to a subdivision with antenna restrictions; moved to an apartment; moved to the Mississippi Gulf Coast; lost a battle with Hurricane Katrina; finally unpacked the Bird after about 8 years in storage.

I can't make it work reliably. As you Bird owners know, the Model 43 uses slugs for various freq and power ranges. The slugs have a small contact spot on them that makes contact with a tiny spring finger inside the meter. On my meter, the spring contact won't make contact.

If I reach inside the hole where the slug is inserted and pull the spring out so it makes contact with the slug, then, I can't insert the slug because the spring finger is in the way. If I bend the spring finger in so the slug can be inserted, the spring finger is not making contact with the slug and the meter won't work.

I can open the meter, fiddle around with the spring, close the meter, try it -- if it works, fine, if not, open the meter, fiddle around, try again.

And -- once I get it working, if I leave it sitting for a few days and come back, it's not working and I have to go through the open-fiddle around-try again process.

When I am not using the meter, I insert the dummy slug that came with it -- which is what the instructions say to do.

Anyone have any suggestions???

Please don't tell me to call Bird -- I tried that -- their customer service is as close to zero as you can get and their repair costs are out of sight, at least for an amateur and occasional user.

Thanks.

If the spring has an opening at the tip you could screw in a sheet metal screw maybe even a machine screw that would raise the height of the spring tip.

Well, since you already called Bird and didn't like their repair costs....

Find a "professional frequent user" that wants to buy a broken wattmeter. They will most likely gladly pay Bird to repair it.

Or...you could find another "ocasional amateur user" that doesn't want to pay to have their quality meter repaired also, and you can buy the broken one from him/her. Then you could the pair as a set of book ends.

Then buy a wattmeter that is intended for "ocasional amateur users" from MFJ.

That spring finger is part of the "line section". I bought a line section for my Bird 43 from Henry Radio for about $60 and it's a straightforward bolt-in repair. Henry Radio sells Bird parts on ebay. I don't think Bird offers or sells individual parts of these "line sections".

Ted,

There was an artical recently (in the past 3 mo.) in QST (I think, or maybe CQ) about a Ham that lives in condo with strict restrictions that uses a screwdriver vertical camoflaged with a fiberglass shroud to make it look and function as a flag pole. He put the radials under loose gravel or along side of the sidewalk.

Hi Clive,

I'm not sure what your design objectives are, but if you have access to an attic, then I have a great recommendation.

It's a extended-double-zepp center fed for 20m.

The results have been far beyond my expectations, especially considering the lousy condition of the bands at this point in the sunspot cycle.

The idea is based on a Cebik article on "the best multiband backup antenna." I hunted a long time and this was the winner for my choice. In his article he makes the case for it - it's worth registering on his site to gain access.

The overall length recommended by Cebik is 88'. But I don't quite have enough to spread it out in the attic of my small house. So I have it setup as a sort-of inverted-v with the ends ran in a zig-zag pattern starting about 1/2 down the slope on each side. I tried to make each half as symetrical as possible, but it's not very close. And to offset the end effects of the zig-zag, I guessed and made the total length 92'. The high current part of the antenna is from the center outward, so that's the important part to keep as straight as possible. The ends are less important.

In my case, it's fed with 450 ohm ladder line down to my basement. Where I have a MFJ-993B autotuner with a 4:1 current balun built-in. Coax fed from that point into the shack.

It will tune all bands with less than 2:1 SWR; but 80 and 160m performance is not good, of course. On 20/30m, the performance is just outstanding!

In the first month of using this, I racked up 15 different DX countries with my FT2K barefoot and in perhaps 10 hours of operation.

When I move into a "real QTH", I hope to put up a full-sized double-extended-zepp on 80M. Too bad Cebik is SK. He really was the Antenna Godfather....

5149. Zepp rediscovered?

Yahoo group: ham-antennas (2008)
Date: 2008-06-24 14:00:49 UTC
From: vaclav sal
Topic: 5144 Message: 5149

I love this recent interest in Zepp. Had one for few weeks "cut" for 20 meters and it worked as expected.
But testing antennas in lousy conditions is a frustrating affair.

One thing bothers me - I believe Zepp was "invented" because it was mechanically practical as a "trailing airborne antenna". Also in "glow in the dark" radio days the finals were of high impedance - maybe easier to match to high impedance end fed antenna.

It seems unnecessary and technically awkward to use high impedance antenna, feed it with 450 ohms ladder line and then transfer this to 50 ohms to make "modern" transmitter happy using balun and antenna tuner.
Kinda long way around the barn.
There is no question that the radiation pattern of double extended Zepp differs from plain dipole, however, is it really an efficient single band antenna with all this additional hardware?

I think real on the air comparison with center fed dipole would answer this question. Of course only on fundamental frequency.

BTW
Is double extended Zepp really "center" fed? I would say mechanically yes, electrically no.

From: Joe Dube
Topic: 5147 Message: 5150

Are you just using the antenna tuner to check for resonace or are you actually using to tune the antenna????? If you are using the antenna tuner and it won't tune it is probaly because you are tuning the antenna on a high voltage point as opposed to a high current point which your tuner is designed for. This can be solved by using a parallel tuning network to use on 75 meters. Another way is to trim about 25 feet of ladderine from the feedline and give it another go. Your mfj tuner will probably work aa bit better looking into a lower voltage point.

Gary,
This antenna does not tune 6 meters.
Anyway a little more info would help.
Are you using a tuner built into the rig?
Is it in a dipole configuration or inverted *V*?
How high?
Cutting 10-12 feet off the feed line should show a drop in the SWR.
I've been playing around with doublets for a few weeks and so far have not
been able to build one that tunes good on all bands

JUst my 2 cents worth

Before you start "Microsoft method" - cutting and pasting feed line -
download free EZNEC antenna modeling program and run "backyard dipole".
Also check out Reflections II by W2DU for same reason.
In either case - expecting "all band" antenna to work decently on 80
meters is a challenge. IMHO - I would build simple wire antenna
especially for 80 meters and after gaining some experience with it I
would fiddle with it to make it work on other bands - not the other way
around.
Good luck.
PS Just curious ☐ how does this "102 feet top hat" performs on 21 MHz?

Topic: 5153 Message: 5153

Hi antenna group,

Here's an easy to tune antenna, using a standard T match tuner with a 1:1 current balun. I use it on 80 through 10 meters. It may even work on 6 meters with the right tuner. It's impedance varies from 74 ohms on 75 meters to 260 ohms on 10 meters. It is made from low loss, ladder line and 14 gauge wire.

See my easy to tune loop at:

http://ph.groups.yahoo.com/group/ham-antennas/photos/view/f4ef?b=1&m=f&o=0

Happy Field Day on June 28!

Hi Vaclav,

I do agree with you on the principle, but in a limited space situation, where the full extended length of a resonant antenna is not a realistic option, then compromises are needed. I would love to have the space for something like what you have. Sweet!!!!

The 88' DEZ proposed by Cebik is a good choice for guys like me with limited space. I promote it because where I live, the challange of finding a suitable antenna kept me off the air for quite a while. It's amazing how a guy can self-justify inaction and blame it on lack of outdoor access. Ha.

Because a multiple-band antenna providing resonant radiators on each band is not a practical option, that means the impeadance presented to the feedline is going to vary all over the place. The open wire feeder does not "fix" the mismatch, but it does side-step the feed-line loss that would be associated with a coax fed solution. Of course, there are effeciency costs on the lower frequencies due to the short length. And in the tuner as well. Not an ideal solution, compared to full-length dipoles in free space. But one that certainly works well, given the compromises.

Regarding the radiation pattern, it's covered in these articles.

http://www.cebik.com/content/fdim/fdim9.pdf
http://www.cebik.com/content/a10/wire/zzdd.html

There is another article by Cebik that goes into the logic of the 88' selection vs. the other common sizes. But sorry I could not recall that location for easy reference.

And in my case of zig-zaging the ends, Cebik has other articles that talk generally about the impact but I've not drawn any conclusion. I would like to model it some day, just to compare what I have vs. a standard dipole, but I'm not that well aquainted with the modeling tools.

This is a buddy of my just a new ham. sence April and ready to take
his Extra then coming Friday night.

He is using a FT 450 AT.
the antenna is up 35 feet in a inverted v and it is working on 6
meter just great. SWR on 6 meter is 3 to 1 then with the turner it
come down to 1 to 1 at 50.125 mhz. 40 meter at 7.205 2.6 to 1 and
with the radio it come down to 1 to 1.

track wire is 90 feet coax going to it is 143 feet. I thank that If I
would add 20 feet more to the antenna it will being the 75 meter in
turner range I will try it today. So thank for all the help...

I'm, confused now because you said it was a doublet antenna.
Doublet antennas are fed with 300-450 line and not coax.
The MFJ site says it a 80 to 10 meter antenna.

Doublet by interpretation of Cebik's definition is a balanced length two-legged antenna that is not specifically resonant, made for wide range tuning.

You could feed it with coax, but the losses would be horrible, so yeah feeding with balanced line of some sort makes a whole ton more sense.

I've fed a G5RV with the choke cut off as a doublet with 450 Ohm straight to the tuner, worked great 80m - 10m.

I'm feeding 135' of wire with a run of coax to a 1:1 balun and 450 Ohm line up to the feed point, also works well. I added that balun to basically keep RF out of the shack due to less than ideal feed points for the window line path.

I like my wide band wires...they won't win me any big-gun contest titles, but that's not my game either.

Basically make the antenna long enough to be 1/2 wl on the lowest band you intend to operate. 135' gets you 80m-10m with 80/40/20 being best on it. 270' gets you 160m-10m with 160/80/40 being the best on it as far as the patterns go.

I've still not found an easy solution to pass 450 Ohm line through a stud wall, that's mainly my issue right now. I have a bulkhead point, but it has station ground wire and coax going through it and will be an aluminum plate very soon to make common ground ties between the coax so feeding window line through that doesn't seem very wise.

If anyone has any solutions to feed 450 Ohm or 600 Ohm line through a stud wall, I wouldn't mind hearing them.

I still think that Zepp or extended Zepp being end fed antenna (historically) should be first classified as high impedance antenna on fundamental and even harmonics frequencies. Ladder line is used not because it has low loss (compared to coax), it is because it matches the antenna feed point impedance better than coax.
I have no quarrels calling double Zepp, either variety a doublet. However, I find the term doublet too non descriptive.
In my most recent experiment - using 20 meters double extended Zepp - I used homebrew 9:1 balun mounted directly at the feed point and cheap RS RG58 as a feed line. When I get rich and famous I will invest in decent antenna analyzer and get some real measurements of this setup.

On different subject - to control stray RF common with balanced to unbalanced coax feed line - simple coax choke always worked for me. But I do not run kilowatts, so the effectives of the coax choke may be questionable in my case. I also adds few pounds of dead weight to the antenna, but it is no big deal when the choke is at the end of the wire anyway.
I cannot wait to try my phased EDZ cut for 40 meters on Field Day! I'll bet it will be a dud on 21 MHz!

Bob,

Do you know how BIG an 80 Meter Dipole is? 131 Feet long!

Then there is the problem of rotating it. The rotation radius will be 65.5"

Without being too cynical, you would first have to buy a house with a much bigger lot.

I looked at your lot on Google earth, and a rotatable 80 Meter dipole would extend from your house over McCormick Bvld.

For the Dipole to be directional, it would have to be greater than 1/4 wavelength above the groung (65.5 feet), so you would need a tower. Since you live so close to the airport, you would have to be more than 1.25 mi away from the airport (1' of height for every 100' from the end of the runway).

Hi Barry,
Well you can sure tell I know nothing about antennas.... lol
Well maybe I'll have to wait till I get a tower in place so I can get a wire up an attached to it.
The way the lots here are teered.... the house behind me is not going to like seeing a beam in their back window. My only way is a wire some time in the future then.
OK... well that does that then.
Thanks for your help Barry. I'm now informed.... lol
Try to stay cool down there and good luck on field day.

How about a Hamstick dipole? That would be about 16ft long with an 8ft
turning radius. I know it's a trade-off, but practical.
I know some dealers sell a mount for two hamsticks as a dipole.

Have a look at my 3-band Hamstick dipole...
http://ac0ok.net/projects/f3bhsd/index.htm
Not the best, but first QSO was from northern Missouri to a maritime
mobile in northern Wisconsin. Not too shabby. (Maybe just luck.)
It was at 12ft above ground, so NVIS... omnidirectional (as far as I can
tell without real testing). Have now removed the rotor & mast stub,
putting it at 10ft. Rotor was kinda pointless. If I want to turn it, I
just loosen the clamps and turn it by hand.
Still experimental.

Rob,

Sam's suggestion of two Ham Sticks will work as an 80 Meter Antenna (as far as something your transmitter having something to load into). However due to it's short length, it will receive poorly and it will be inefficent as a transmit antenna.

There aren't very many 80 Meter antennas that hams can build that will be directional due to the close proximity (in wavelenght) to the ground (phased verticals being the exception).

You might consider an 80 Meter horozontal loop if your lot will accomodate a 65'X65"X65'X65" wire run. With a tuner it will work on 40, 20, and 10 Meters also.

Or, you can do like I did, a 120' end fed long wire (ran diagonally across my lot) with a tuner. It works on 80, 40, 20, and 15 Meters.

How about a Hamstick dipole? That would be about 16ft long with an 8ft turning radius. I know it's a trade-off, but practical.
I know some dealers sell a mount for two hamsticks as a dipole.

Have a look at my 3-band Hamstick dipole...
http://ac0ok. net/projects/ f3bhsd/index. htm
Not the best, but first QSO was from northern Missouri to a maritime mobile in northern Wisconsin. Not too shabby. (Maybe just luck.)
It was at 12ft above ground, so NVIS... omnidirectional (as far as I can tell without real testing). Have now removed the rotor & mast stub, putting it at 10ft. Rotor was kinda pointless. If I want to turn it, I just loosen the clamps and turn it by hand.
Still experimental.

Bob,

Your lack of knowledge about antennas is understandable.

Congratulations on your very recent upgrade to General Class.

You will leard alot about Radios, HF, and propogation as you venture into the areas that your new prividleges permit.

I would however, suggest that you start out on 20 Meters. The antennas are alot more manageable and you can work all states as well as a lot of DX.

Well your Titan is about 40ft short on 80m, it needs to be closer to 65 ft tall not 25. Anytime you make an antenna shorter you lose some efficiency. You can put up two 80m dipoles 90 degree to each other and switch them. If you want to rotate then think about a 20m beam or a tri-bander , you will have a lot of DX contacts on 20. You would have to build your own set up to rotate on 80 and I don't think that is a project for a first try. The wind loading would be quite large so every thing get bigger to support it. I made my own 5 band dipole (75,40,20,17 and 10). I could not afford a Titan.

My first novice band 80m was a vertical made from PVC , spiral wound and a small capacitor hat, it was also about 25ft tall so I know what you mean about wanting more. The next was a Slinky in the attic , not much gain with that set up.

Hi all,
I'm rather new to the group. I was wondering. Does anyone have directions on how to build an 80 meter rotateable dipole that a beginner could build.
I have a gap titan dx vertical but it really lacks on 80 meters.
Anyway I thought I'd try my hand at building my 1st antenna if I can get some easy to build directions.
Thanks and 73

Hi,
First, I'd like to say thank you to everyone that has sent back comments for me. I have printed them all so I can go back and re-read them several times.
Barry, I want to thank you also for all of your suggestions.
The reason for the 80 meter dipole in the 1st place was because I have a bunch of friends that live in California and we all get on at night and swap lies. I just thought it might make it better for me on the receive and also on the transmit side. The gap titan dx is like I said before... some what lacking in performance on the 80 meter side for some reason.
I can see now that I will need to consider all these other options.
As for your first idea Barry of a new house.... I don't think that will work..... this one is only 4 years old and my wife would kill me.... HiHi.....
Anyway... thank you again.
73, Bob KE6KJD

Use plastic water pipe...
Drill the holes downward a little so the rain will not run in.
Use a good calk around the pipe to seal the pipe in.
It would also be good to be able to ground your antenna outside your
building when you are not using the antenna. A knife switch works well.
Also it works well to terminate outside the building and then using
simple alligator clamps and jumper wire to ground and disconnect your
antenna.

Bob,

Maybe you should take a look at an 80M inverted V. They take up less space and are omnidirectional. Actually from your QTH top most of CA should not be a big haul with a plan old standard dipole. Are you running an amp?

Another antenna that you might want to look at is a Cobra Ultralite Junior. It covers from 10m to 80m. It ia very effective. I have the Ultralite Senior and am very pleased with it.

Hello,

I have been using a home-built 1/4-size Cobra for a couple of years now, and I am quite pleased with the performance for its size.

Has anyone ever tried to use one leg of the 3-wire conductor Cobra dipole, and configure it as an end-fed?

Actually, MFJ says it is a 160 to 6 meter antenna (160 as a top-hat).

This antenna includes 100 feet of ladderline, so I don't know why you have so much coax. Is there a balun?

If you use the ladderline the impedance seen looking into it could be way up in the 100s of ohms (even 1K ohms if the SWR is 2.2:1), which might present a severe mismatch to the coax unless you use a 9:1 or at least a 4:1 balun between them. 2.2:1 SWR in ladderline can become 20:1 SWR in the coax without the right balun.

Andy

I have a GAP Titan myself and went through this a year or so ago.

For local/regional 75m rag chew, which I happen to love, a vertical is all wrong. The takeoff angle is too low and you have tremendous loss due to cross polarization vs the horizontal wires that most people are running on that band.

You can get a really great signal by simply making a 135' dipole fed with either ladder line to a tuner for wide band use, or fed with very short coax from the tuner, just outside the shack wall to a 1:1 balun and then ladder to the antenna for 80m-10m coverage (manual wide range tuner needed for either one) or a resonant dipole, coax fed for 80m only.

Take one of those options and hang it wherever you can fit it, mine is all of 25' off the ground and you will be good for 10 over 9 signals for the local region with 100W.

For regional 160m or 80m, you want a relatively low antenna to put the radiation straight up...it basically comes back down in what I like to say is an umbrella pattern covering a few hundred regional miles.

For DX on 80m or 160m you want a vertical so you can get low takeoff angles more easily and get over the horizon. For a dipole to perform like this you need outrageously high supports for these two bands, that most of us can only dream about.

You can end feed a 66' length of wire from a tuner against a ground as well for 80m. RF in the shack is a bit of an issue with end fed wire from a shack based tuner though but at 100W it can be done. I tossed some wire over tree branches and tied it to a fence as my first try and it worked pretty well.

One other mention. This time of year is bad for 80/160 due to static crashes from electrical storms. So even if you have a 10 over 9 signal, don't get discouraged if people can't hear you, they are not summer season bands really so it is normal.

I put it off for about a year, but finally broke down and got an amp so I would be over the band noise more effectively. If you find you like the band and become a regular...an amp is really valuable on these bands.

Hi Chris,
Thank you for your input and help. I'm looking at all of this now and will have to decide which side of the house will be best to do due to the size of my lot. I'm leaning towards the closest side to where my radio shack is. Less feed line looks like the better option here.
I recently aquired a Yaesu FL-7000 from an estate sale and it is now on it's way to Bill Grassa in Florida for the upgrades. I'm sure it will be a help when I get it back.
I just wish there was a good spot to pick for a wire. I'll just have to pick a spot and hope that the neighbors don't hemorrhage over seeing it. They are not happy seeing the Gap Titan DX now.
Thank you again.

My GAP is a real eyesore compared to any of my wire. The wire, if you use black, is nearly invisible. The only thing you see of my wire is the window or ladder line going to feed it.

5183. 868 mhz Yagi

Yahoo group: ham-antennas (2008)
Date: 2008-06-26 21:45:20 UTC
From: hurleyvcr
Topic: 5183 Message: 5183

I am building a 11 element Yagi tuned for 868 MHZ using the calculations based on this web site http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=11183.
I have all the elements and boom cut exactly as computed.What would the input impedance be for this yagi,Do I really need a matching network for receiving trunk systems and what feed line could I use for say under thirty feet?
All element diameters =.181 in.,boom dia =.50 in.

5185. two beams

Yahoo group: ham-antennas (2008)
Date: 2008-06-29 01:05:38 UTC
From: ke0pv
Topic: 5185 Message: 5185

I have a TH11DX Hy Gain beam on a tower at 55 feet. I have another 55 foot tower on which I would like to put a Steppir DB 36. I really dont want to take the TH 11 DX but if I have them both up they will be only about 55 to 60 feet a part. Does anyone know about seperation of two tribanders on different towers? I could of course just replace the TH 11 DX and sell the second tower since it is not up yet. But, I would like to be able to use both beams.

Any help would be appreicated.

Not an answer to your question at all but - did you order
your DB-36 at Dayton? Just curious - I was with the crew
that brought the trailer from U S Towers and installed it
that was supporting the antenna there -- I visited with a
lot of people about it. Just curious if I had met you - 73

I ordered it prior to Dayton but was there getting more information.
I actually have about 72 feet of seperation where I would like to put
the second tower and could maybe get up to 100 if I went somewhere
else but that location is in line with the "view" of the lake and I
don't think my wife will go for it.

I would use it and see if there is any major interaction, I would disconnect the other antenna from any equipment and see if antenna #2 will tune , so as to not damage any equipment connected to antenna #1. I have run a few yagi's that close without a problem.

From: Phil Bader
Topic: 5005 Message: 5189

I have a basic theory for a ham starting with antennas. Keep it as basic as possible. The most basic, and affordable would be an inverted V, as high as possible,as long as you have room for, fed with 450 ohm flat "window line" down to an antenna tuner. That's it: one all band HF dipole. Simplicity. As experience and bravery develope, expand on more complexed arrangements. It's done many a ham well.

Phil,

I'd like to offer that for simplicity sake, feeding the inverted V (or dipole) with coax would be more simple. Perhaps not as efficient as 450 ohm line but simpler and cheaper. One can always "upgrade" later

5191. RE: [ham-antennas] A Couple HF Dipole Questions

Yahoo group: ham-antennas (2008)
Date: 2008-07-01 13:36:06 UTC
From: James Fogg
Topic: 5005 Message: 5191

The ladder line feed, though a bit more complex than coax and a 1:1 balun, provides additional options for radiation and resonance. It would allow, for example, an 80M dipole to be tuned for 160M. My 80M coax fed dipole is hopelessly unable to be tuned to 160M. My tuner instantly arcs internally no matter how I set it up. Dipoles are famously bad at working at wavelengths longer than their physical length. Having a feed line that can radiate can solve this limitation.

There are certain lengths that one shouldn't cut a ladder line feed to. You don't want your feedline to appear resonant at the dipole's resonant frequency. There are charts that show feedline length recommendations for each dipole length/frequency.

5192. RE: [ham-antennas] A Couple HF Dipole Questions

Yahoo group: ham-antennas (2008)
Date: 2008-07-01 14:15:08 UTC
From: Rich Schmuke
Topic: 5005 Message: 5192

I want to add my 2 cents worth (or what ever the amount is toady due to inflation). I am a nut when it comes to trying antennas. As soon as I build one I am thinking about the next, I rather make and build than rag chew. I must agree with John, for a start keep is simple. If you toss up a simple coax dipole and it works first try you will go on to more involved set ups. If it does not work and you buy one you can miss out on a great feeling from amateur radio of building things on your own. My 5 band dipole took more tuning to get it on 80, 40, 20, 17 & 10 , PSK31 frequencies with 1.1:1 all bands but I can say I built it not just I bought it. You can cut a dipole according to the numbers and it will work. On my 5 band I had a lot of interaction on the higher bands and had to change lengths.

So simpler is better for a first try or as some say use the "KISS" method .

KD0ZZ , Rich

I am not getting older but having a propagation problem with the neurons in the grey matter.

Any errors in spelling or facts are tramsmission errors

Phil,

I'd like to offer that for simplicity sake, feeding the inverted V (or dipole) with coax would be more simple. Perhaps not as efficient as 450 ohm line but simpler and cheaper. One can always "upgrade" later

I have a basic theory for a ham starting with antennas. Keep it as basic as possible. The most basic, and affordable would be an inverted V, as high as possible,as long as you have room for, fed with 450 ohm flat "window line" down to an antenna tuner. That's it: one all band HF dipole. Simplicity. As experience and bravery develope, expand on more complexed arrangements. It's

done many a ham well.

From: G B
Topic: 5193 Message: 5193

Hello,

I ordered some saddle clamps and other antenna
parts from a CB antenna parts supplier a year or
so ago, but I cannot find their name anymore.

Does anyone know who I am thinking of?

I am not impressed with DX Engineering prices!

Rich can you share your final cuts on your 5 band . Is it an
OCF/Windom or a tuner driven dipole?

We thru up a 80/40/20/10 OCF for field day and it worked like a champ
using a 4:1 balun and the 33/66% offset, but while flat on the upper
bands - had some VSWR spikes on 75M at 60 feet horizontal.

5195. RE: [ham-antennas] Re: A Couple HF Dipole Questions

Yahoo group: ham-antennas (2008)
Date: 2008-07-01 17:01:33 UTC
From: Rich Schmuke
Topic: 5005 Message: 5195

Danny , it is direct coax fed system, no tuner is needed. If I move off frequency of the PSK31 then the tunner in the rig can handle the small change. I tried a Windom but it did not outperform a straight dipole or my 40m vert but the Windom had two baluns in the set up.

I would have to take it down to measure the cut length. I knew they would interact and made them all a little longer and trimmed each one to the frequency I wanted with a SWR meter. The upper wire (80m) is cut to normal length , it is 14ga copperweld, The others are14 ga copper with home made spacers made from cut up PVC. After the 80 I trimmed the 40m and went from there. I split the PVC length ways into quarters also. One problem I had last winter was when it was solid ice the SWR went through the roof as the ice formed a resistor between the wires. The spacers are about 24" apart to prevent twisting from the wind

5196. HF wire antenna made from Polywire? (electric fence wire with a difference)

Yahoo group: ham-antennas (2008)
Date: 2008-07-01 18:59:34 UTC
From: RMC
Topic: 5196 Message: 5196

Hello All

A search though the group archives highlights references to antennas/counterpoise systems made from electric fence wire, but not the sort of electric fence wire I'm looking at buying. Please could you give me some opinions?

http://www.electricfence-online.co.uk/ishop/1047/shopscr72.html

This URL shows the general idea - a polyurethane string which has weaved into it a number of thin stainless-steel cores and sometimes some Cu/Ni cores too . A typical wire might have three or six s-s cores of approx. 0.1mm or 0.2mm per core, leading to a DC resistance of approx 7R/metre.

The things is, the O.D. is approx. 2mm and the breaking strain is 70kg: for example:
http://short.zen.co.uk/?id=a7d

The idea is that the antenna will be stealthy , cheap and strong.

As far as I can see, the loss resistance for a resonant antenna (say a half-wave dipole) is dominated by the ohmic losses in the first few per cent of conductor, with diminishing I*squared*R losses as you go along. I can do some sums looking at skin depth in stainless steel and get some ideas about the losses compared with the radiation rsistance and that'll give me an efficiency.

Has anyone any experience of building wire antennas using such thin conductors? My forward power will always be less than 100W at HF.

Thanks for any observations or comments

Richard, M1JKL

Topic: 5168 Message: 5198

If you really want to cover all of those bands with a single antenna, get an SGC auto-coupler and then get lots of wire up in the air, either a very large loop or a random wire with lots of counter-poise wires buried and the coupler grounded to a copper rod. I've tried all of the antennas you mentioned in your question and continue to use some but for true multi-band antenna I think the SGC coupler/wire has fewer compromises.

And if you're just getting into PSK you're going to love it. I can actually "play radio" while family members are in the same room.

I use this stuff for electric fencing of goats and horses. I never considered it as antenna wire because it's more expensive than fence wire and might be an electrically wide diameter. The diameter of the wire is a factor in dipole calculations, but for most normal wire it's not a significant factor. As you increase the diameter it becomes significant.

As for stealth, I continue to walk into my 14ga black insulated inverted V, even though I know it's there. It's very hard to see. Polywire is bright white or orange and white so that animals can see it.

Another interesting material is polytape. It's up to 2 inches wide and might significantly alter the behavior of the antenna. I don't know if it would alter it in a good way or a bad way.

Anyone know the effects of radiator diameter in a dipole?

Hello,

Well I first had to figure out what a saddle clamp was! I call them u-bolts :) The last time I needed one I went to the auto part store and asked for a muffler clamp. Don't know if it would be the correct size but its worth a shot. Also check your local hardware store I know they have u-bolts but I not sure about the "clamp" part.

Thanks for the replies. The aspect that I am not so sure about is the DC resistance being that much higher than copper - 3 x 0.16mm thin stainless steel as opposed to the same sort of copper (or larger diameter).

I haven't yet worked out the skin depth in stainless steel, but the circumference of 3 lots of 0.16mm = 1.5mm which is equivalent to 0.5mm solid
wire. I wonder how the resistivity will compare at HF?

The polywire I plan to use is white so against the sky it should be difficult to see.250m for ?9 is pretty cheap, compared with hard-drawn copper for ?25 for 50m!

Hello,

Well I first had to figure out what a saddle clamp was! I call them
u-bolts :) The last time I needed one I went to the auto part store and
asked for a muffler clamp. Don't know if it would be the correct size but
its worth a shot. Also check your local hardware store I know they have
u-bolts but I not sure about the "clamp" part.

I guess I would want to know a little bit more about the capacitance issues.
I would think all those strands insulated from one another would make 6 or 9
parallel capacitors.

Hi,
I needed a couple last year... went to the local boat shop and they were stainless steel..... a bit pricy..... but when you need them you'll pay a few dollars more.
take care.

5209. Antenna Coax Grounding - Need input

Yahoo group: ham-antennas (2008)
Date: 2008-07-02 10:55:29 UTC
From: John P.
Topic: 5209 Message: 5209

I need input on grounding.

The setup here.....

2 Fan dipoles separately fed with RG8x. about 40-45 foot to ground.
At that poing (50 feet of coax) a ground rod is driven and all the shields are bonded to this ground.
Another 50 feet of RG8x goes undergroung (thru PVC pipe) to house.
Another bonding point just inside house entry for all the shields.

THE QUESTION.

Pounding another 8 foot ground rod at the house entry is impossible since it comes out under a deck that is 4 foot high and 8 foot wide.
I can use 1) a 3 foot length pieces of pipe, 2) cut a standard 8 foot grounding rod down, or 3) pound several pieces of welding rod bound together.

Any suggestions for this "entry ground" would be appreciated as I'm sure others have encountered similar problems.
Note that I do realize that bonding it to house ground is not possible (40 foot away) and obviously not to the ground lug of the power outlet either.

Thanks in Advance.

The strands are woven, so they continually cross each other. It would be similar to using coax braid for a dipole, but with fewer strands.

I'd only be concerned with the material of the wire. Did you say
they're stainless steel? That's not a great conductor. Efficiency
could suffer.

Any reason you can't use the 26 gauge stranded copperweld offered by
many antenna wire suppliers? It's pretty darned tiny and lightweight.

The poly/woven electric fence wire we can get around here is bright
yellow - it is intended to be very visible, which would work against
your objective.

5213. G5RV changes

Yahoo group: ham-antennas (2008)
Date: 2008-07-02 16:51:15 UTC
From: noswadplease
Topic: 5213 Message: 5213

I currently have a G5RV 204ft in a vee from the roof (15') to two trees about 55 ft apart. The ends of the antenna are about 17 ft up with a wire making a closed loop going up about 28'. My plan is to put up two 48' fiberglass poles near where the antenna ends. The antenna will start at 15' high and end at 48'. I have two questions. I would need to make the antenna longer to reach the heighth. Would this adversely affect the receiving or make any improvement? I am also considering closing the loop at 48ft. I am wondering at this height would it make much of a difference? It would definitely be easier not to, than trying to get a wire thru branches at 48ft up. I am using the antenna for receiving only. The antenna has 64 ft of ladder line and 140ft of coax, lightning arrestor and grounded of course with an Mfj 956 tuner. Any input would be greatly appreciated.

I'm not understanding this, so the ends drop to 17' and you have the antenna tied to a wire loop at 28' high also?

Just tie off support ropes to the end insulators? No need to lengthen the antenna legs, just make the tie-off ropes longer.

Hmm receive only, well if you connect the ends of the dipole to form a loop, you may notice better noise rejection characteristics.

Until I 'get it' with what you mean about the loops you mention, I'm still a bit in the dark to really comment.

My G5RV had insulators at the end of each leg, through those, I put support ropes. I also had a rope through the feed point at the center to raise it up.

Hi Chris,
I have the apex of the vee attached to the peak of the roof which is 15' high.
The antenna spreads into a vee 102' long 17' above the ground. At the end before the insulator I attached a wire going up thru the trees about 28' high and then attached to the other side to make a closed loop. Sorry for any confusion. Ed Dawson

Ah o.k. for receive only, using a tuner, you can pretty much do what
you want as the tuner will fix the resonance if you change the wire
length.

Not 100% sure but from my dealings with McMaster-Carr you might learn to like DX Eng. prices. But the McMaster-Carr (Yellow Bible) as many call it is indispensable for hardware brainstorming and a great comparison for pricing.

they are and always have been hard to get. But the McMaster-Carr Yellow Bible as I call it is indispensable for hard ware brainstorming and a great comparison for pricing. If you have a large used book store around your area, you just may find a copy of the "bible" Often a good source for vintage QST, and reasonably current ARRL publications. A good portion of my technical library QST's Some 50 years worth, along with ARRL handbooks and antenna books from ARRL and others have come from 2 used book outlets just a few miles form home.

Good luck

Garth N2BMP

Well. Usually the idea is to have all grounds at the same potential. A ground stake at one end of a run, and another ground 50 or 100 feet away may not have (probably won't have) the same electrical potential. The cable and telephone co's like to have their cable entrances to the house at the electric meter/weatherhead's ground point,and strap to that,thus tieing the houses electrical ground to their cable's ground keeping both at same potential.
Remember, with a lightning strike,there will be a "ground current" set up in the earth around your QTH. With a small resistance over a hundred feet could translate into thousands of volts. I usually strapped all my grounds together if possible: The tower base, coax shields, on into the shack to my equipement,and also to the shack's (home's) electrical ground. I had a "buss bar" or a 4 fot length of copper tubing behind the rig, with heavy copper braid attached with radiator clamps, and on to each peice of equipment.
Note also, that in most areas a typical 6' ground rod offers little reduction in resistance to ground. Usually an irrigation well casing,or series of rods driven into earth and strapped together is preferred.
Lets say you have a small satalite dish out in the yard on a post. At that point you have one ground rod driven,and attached to the dish. Now the coax runs across the dirt, into the home,and is grounded behind the box at the wall. That wall's receptical ground,and the disk's ground in the yard may be way different,and thousands of ohms apart,hence thousands of volts apart in the presence of ground current due to a local strike. That POTENTIAL difference is what can cause the damage.
A good and proper grounding system will help with rcvr static, shock hazards and lightning dissipation. Sorry for the long winded response-

Subject: [ham-antennas] Antenna Coax Grounding - Need input

I need input on grounding.

The setup here.....

2 Fan dipoles separately fed with RG8x. about 40-45 foot to ground.
At that poing (50 feet of coax) a ground rod is driven and all the shields are bonded to this ground.
Another 50 feet of RG8x goes undergroung (thru PVC pipe) to house.

Another bonding point just inside house entry for all the shields.

THE QUESTION.

Pounding another 8 foot ground rod at the house entry is impossible since it comes out under a deck that is 4 foot high and 8 foot wide.
I can use 1) a 3 foot length pieces of pipe, 2) cut a standard 8 foot grounding rod down, or 3) pound several pieces of welding rod bound together.

Any suggestions for this "entry ground" would be appreciated as I'm sure others have encountered similar problems.
Note that I do realize that bonding it to house ground is not possible (40 foot away) and obviously not to the ground lug of the power outlet either.

Thanks in Advance.

Phil,

Thank you for your articulate and detailed reply.

I do know and agree that bonding the grounds is the best way to go.

What I am trying to do - to list just a couple of things is:
1) allow for grounding as close to the point that the 2 coax lines go under ground;
2) allow for grounding at the station or as close as possible;
3) reduce the possible impact of nearby lightning static discharge;

I am trying for the best compromise with the greatest reduction in the probability of damage.

I do realize that a for a direct hit anything is possible. BTW, I always disconnect ALL antennas when I'm not operating ---- & I do not operate in thunderstorms either. The only 100% sure thing is to become an SK and then have no worries - not an option though.

OK- At the antenna base at the 50 foot point where you bond the coax grounds together to a ground rod, I would bond at least a #10 copper wire,and feed on thru the PVC with the coaxes,on to the house entry point, where you again bond all shields to this #10 wire,and again at that end feed the wire to a ground at the house end if possible. That bonds every end the same. and with the house electrical ground.

Phil,

I like the suggestion - thank you.

I will probably have to vary slightly since the entry point is before the Service Ground.

1) Coax common at ground rod;
2) 50 feet #10 to bonding point/common point under deck;
3) 35 to 40 feet #10 to Service Ground rod
4) From #1 a 3 foot # 10 to 2nd Coax bond (from here I will get my station ground also)

Sounds like a good plan. Now just to locate a a "good" price the #10 wire. Don't worry, I'll not take down any power transmission lines even though I used to work for a Utility Company (HV Transmission Planning & Analyst).

BTW, the Service Ground is #10 aluminum.

Thanks Again!

5224. Best Antennas for Use in a Valley

Yahoo group: ham-antennas (2008)
Date: 2008-07-03 01:07:49 UTC
From: ash_lee52
Topic: 5224 Message: 5224

I live in the bottom of a mountain valley, surrounded on the east and west by mountains rising between 1,000 and 3,000 feet above the valley. To both the east and west these mountains rise between 15 and 20 degrees from what would be a normal flat horizon.

I'm searching for the best antenna for DX from this location. I know that most DX signals arrive at under 8%... which means I have a definite theoretical problem. On the other hand I have worked Europe, Japan and Australia from this location, so I know I can get some east/west propagation. My best antenna so far is a Buckmaster Off-Center-Fed-Dipole with legs of 90 and 45 feet, set as an inverted V. I've had some success with a 20-meter Half Square, Hustler 6BTV, a Sigma 5 and a rotating dipole as well.

But I still hear much less than I did from my previous location... so I know I don't have an optimum set-up. I can't put in a tower, so Yagis are probably out of the question.

Does anybody have any wisdom on what works best from a valley bottom? Do I want an antenna that maxes its signal in the 20-25 degree range. Or will the signals from a lower focused antenna travel up the mountain sides?

Hi Ash,

The issue that comes to my mind is the bottom of the solar cycle doesn't help. Since and all band or multi band antennas are compromises have you thought of puting up a inverted v or a verticle resonant on just 20m? Just a thought...

I would use a dipole and keep it low, 20 feet or so. That will make for a high angle of radiation (NVIS). My first 80M dipole was 20 feet high and covered 800 ~ 1000 miles with no trouble. I reconfigured it into an inverted V at 45 feet and I almost prefer the solid predictable performance the high angle of radiation gave me. At higher frequencies 20 foot high dipoles start to become low angle radiators.

I have no problems at all reaching all over the US, so I figure an NVIS antenna isn't necessary... my challenge is to hear/reach Europe from the bottom of a valley in Colorado.

Will NVIS antennas simply get more RF out of the valley... or is there a logic on trying to use low angle antennae and get them to defract on the hills? What would a beam tilted slightly upward do, for instance?

Jim,

Thanks, I be looking there. I need only about 100 to 120 feet.

BTW, I use #12 insulated for all my dipoles and did you know that the THHN insulation reduces the velocity factor by 3-4% thus reducing the dipole length accordingly?

Maybe You could use some of the #10 for a dipole (Hi Hi)

73's

John,

I didn't need 500' either but got the 500' roll for less than buying 200' up
at the local hardware store.

I guess I could use it for ra dipole but bare copper is a lot cheaper

From: Rich Schmuke
Topic: 5209 Message: 5232

Before you put up any wire with insulation that might degrade over time why don't you strip it first. I strip RG-11 CCTV type all the time for 14ga Copperweld in it. Drill a hole the OD of the wire in a 2x4 , cut a slit with thin blade like a hack saw down to the slit, put a blade from a utility knife in the slot with the point set to slit the insulation. Put a c-clamp the hold the blade in the slit pull the wire through. I put the 2x4 in a vice, support my roll of wire on a wood dowel supported by jack stands and strip away. If I can slit coax, regular THHN wire is no problem.

KD0ZZ , Rich

I am not getting older but having a propagation problem with the neurons in the grey matter.

Any errors in spelling or facts are tramsmission errors

Also, if you used it for a dipole you would probably need some really strong trees or supports (Hi Hi).

I was fortunate as far as antenna wire. When we moved the factory, they pulled about 1000 feet of #12 insulated (THHN) wire from conduit and were going to toss it. It was varing lengths - 12, 18, 20 foot. But it was plenty to make 2 fan dipoles - a 75,40, 20 and a 20,15. I still have quite a bit left over.

The capacitance between strands is not an issue, because the signal doesn't exist BETWEEN strand wires. All strands carry essentially the same current & voltage, so capacitance between two equi-potential points is a non-issue.

If capacitance between strands were a problem, then using non-insulated strands (i.e., capacitance goes to infinity, shorting them together!) would somehow be even worse.

Andy

I think you are right. Besides, the strands aren't specifically woven to occupy a particular place within the cross section (Litz wire of courseis intentiaonally spun in certain ways) and no doubt join and separate along the lnegth. I'll find out when I buy some.

I've had a look at a PDF written by David Jefferies (http://personal.ee.surrey.ac.uk/Personal/D.Jefferies/bio.html) in which he shows that thin s-s wire certainly is more lossy than Cu wire - BUT the losses involved aren't drastic. Here are some figures to play with, assuming the TAB spacing makes this chart readable once it has been emailed:

Watts of heat dissipated for 100W input power, half wave dipole , 12AWG

material	160m	40m	10m
Silver	4.1	2.1	1.1
Copper	4.3	2.2	1.1
Brass	about 6.2	about 3.2	about 1.6
Tin	10.2	5.3	2.7
Lead	13.5	7.2	3.3
Gold	4.8	2.5	1.2
Aluminium	5.3	2.7	1.4
Aluminium alloy	about 6.7	about 3.5	about 1.8
Iron	about 77	about 63	about 46
Stainless steel	8.4	4.4	2.2
Tin-lead solder	11.5	6.1	3.1
Zinc	7.6	4.0	2.0

To contrast antenna efficiencies for a perfectly matched L/2 dipole - 98.9% using Cu at 10m wavelengths dropping to 97.8% for stainless steel.

In my case, the thin "tinsel" strands will further reduce efficiencies due to the skin effect and it's worse still in steel. Loss resistance in Cu at 40m is about 1.6R for a L/2 dipole, and about 3.3R for stainless steel (304 grade). That's for 2mm dia wire (12AWG).

So ... I think I will try polywire and see what happens.

Thanks

RIchard, M1JKL

Subject: [ham-antennas] Best Antennas for Use in a Valley

I live in the bottom of a mountain valley, surrounded on the east and west by mountains rising between 1,000 and 3,000 feet above the valley. To both the east and west these mountains rise between 15 and 20 degrees from what would be a normal flat horizon.

I'm searching for the best antenna for DX from this location. I know that most DX signals arrive at under 8%... which means I have a definite theoretical problem. On the other hand I have worked Europe, Japan and Australia from this location, so I know I can get some east/west propagation. My best antenna so far is a Buckmaster Off-Center-Fed-Dipole with legs of 90 and 45 feet, set as an inverted V. I've had some success with a 20-meter Half Square, Hustler 6BTV, a Sigma 5 and a rotating dipole as well.

But I still hear much less than I did from my previous location... so I know I don't have an optimum set-up. I can't put in a tower, so Yagis are probably out of the question.

Does anybody have any wisdom on what works best from a valley bottom? Do I want an antenna that maxes its signal in the 20-25 degree range. Or will the signals from a lower focused antenna travel up the mountain sides?

WW0AL
Ash

All thoughts and experiences welcome.

Have you determined the elevation angle to the horizon in the direction(s) you want to operate? Since you are already getting out to Europe and Asia, I'd have to guess your view is not blocked as badly as you may think. Perhaps your mountains in those directions are distant enough so that the angle is reasonably low ... low enough for you to have had the success you have.

Unless I'm mistaken, neither Europe nor Japan is on an east-west line from you, as the photon flies.

While there may be some diffraction over the mountain peaks to get beyond your horizon, I don't think there is much *you* can do by choosing different antennas to help that. AFAIK there is no magic to make radio waves diffract around/over objects. But I'm no expert on propagation details ... for example if vertical or horizontal polarizations diffract better. (As a guess, one might think that horizontal polarization is more likely to be attenuated by skipping near to the surface.)

If you had a beam, I'd guess that it might work better if tilted to just above the mountaintops.

NVIS isn't going to help you get far. It would get you out of the valley (which you are already doing), but not at a DX-appropriate angle.

Regards,
Andy

5240. antenna query

Hi folks:

My new QTH near Guadalajara, Jal, Mexico is a tiny, cement structure, part of a housing complex. This is NOT my NYC apartment up 85' with the 135' 8om dipole, alas. OK:

Here are the dimensions of the lot: 11m long, 4m wide, and two storeys tall. The little house has a somewhat pitched roof (about 5 degree slopes), two directions. The apartments are all stacked together and share walls. Yet, this one is on the end of a group, and has a free, proper wall that faces a courtyard, so I think mebbe can run some feed up to where the two slopes of the roof meet. This high point is at 5.5m from ground level. The "shack" is on the first floor.

I want to operate 80-10m, but I'll settle for 40-10m. I run CW and PSK31, try to keep it 50w or down to QRP levels. Yes, I have a transmatch and a Hendricks QRP tuner.

My XYL--who owns it--tells me I can use an old 2m tv antenna mast up topside to attach things to. Hmm...a total high point of 8m.

Any ideas for a cheap wire antenna? Slanting, sloping end=fed? I like direct single wire feed or use of 300 ohm tv line, rather than coax cable.

As for "ground", well, they have copper water pipes at ground level going out to the street. At what point this becomes pvc (if at all) is unknown to me. There is a copper gas line going to a stationary tank, too, that parallels this water pipe for a spell.

Street AC is buried around here, right next to the house on the 'free side' mentioned above. Cable TV and telephone pole is right next to the house. Worry about TVI into the phone lines, of course.

best,
Roberto "Rob" Barnard

Have you considred using a pair of Hamsticks in a dipole configuration for 80 meters?

It may be a compromise but it is better than QRT. They sell a dipole adapter bracket for the dipole configuration. Total cost is probably about $75 - $25 for each of the 2 ham sticks and the bracket.

I made a end fed wire antenna using 66 feet of wire
The little tuner used a poly type cap but it has been up to 25 watts with no warming up
The core is a T-68-2 with 24 turns of # 20 GA wire and a 3 turn link.
It loads 40 to 15 meters on that single wire.
I would take the wire to the mast then slope the remainder down
Some hams are running the antenna in a inverted V configeration.
Ham sticks around here are 14.95 each.
The bracket is 12.99 but I never tried that dipole configuration.

Hi all,

I´m thinking in install one G5RV antenna in inverted V configuration.

Anyone on the list have experienced with G5RV inverted V.

Anyone knows if the ladder line descending inside or hooked outside
the mast can be a problem the for a good matching impedance of the
antenna? or even the SWR ?

Any tip will be very helpful.

Thank´s a lot, 73 and many DX.

I am running a G5RV inverted-V at about 22ft with window feedline horizontal.
Feedline is secured to a dacron line from the top of the G5RV mast (fiberglass military mast) 75ft to my tower.
Using RG8X coax from balun to tower, then Andrew CNT400 coax to shack.
Just replaced the main coax today... was 9913 and had gotten full of water and wouldn't tune. Now tunes to almost zero SWR.
Don't know who made mt G5RV... bought it via eBay. Get good coverage...
NVIS covers states of Missouri and Iowa quite well.

Hello Paulo,

I have the 204ft G5RV in a vee. The antenna came with 64 ft. of ladder line and recommended 140ft. of coax. It works very well on most bands. I did eventually run a wire from the end of the vee to the other to makes it a closed loop. You can do this if only dx'ing and not transmitting. It di make it somewhat quieter. Right now I have it about 17 ft. up, but I am gathering poles, etc. to raise the ends 48ft. If you can use the 204ft. G5RV It would be the best. Connect a lightning arrestor between the ladder line and the coax. Ground it well and use a tuner. An Mfj-16010 or Mfj-956 can be picked up on Ebay relatively cheap, even new they are not that much. It definitely works well. I also am running an AOR SA-7000 at 41ft. high and their is little difference switching back and forth between them. If space is an issue you might want to consider the SA-7000. Even though it cost more You don't need all that coax so it balances out in price. I would still use a tuner with either one.

This is where I bought might good info here.
Good luck Ed Dawson

5248. Beam performance

Yahoo group: ham-antennas (2008)
Date: 2008-07-06 03:04:35 UTC
From: Kenny Wyss
Topic: 5248 Message: 5248

I have made a lot more progress on my tower project. The tri-band beam is up, as well as my guy wires. The past few days I have been playing around with the beam a bit, and am a bit discouraged at what I have seen. The beam is used, so before I hauled it up there, I totally worked it over. I cleaned the entire thing with steel wool, put all new connectors and wire where applicable, and opened up the balun box and cleaned it well. SWR is decent. The antenna is a Hy-Gain TH3-MK3.

There have been instances where I can be listening to a DX station on my G5RV, rotate the beam toward the station, switch to the beam, and find that the G5RV is performing better on receive. There are times when stations come in better from the back of the beam. Only during a few instances have I noticed that the beam seemed to outperform the G5RV. I put the beam up at about 34'.

Should I chalk most of this up to propagation or could I possibly have a problem? I never did have the traps checked, so I am not 100% sure they are all okay.

Thanks and 73,

Kenny, KB0NPW

Ken, I'm not sure of your problem, but consider: Your G5RV is probably inverted V,so there's a vertical polarization element there,and your beam is horizontal. Also, no one knows exactly what propagation /polarity the incoming signals are. After all, take a baseball, mark an "X" on it, bounce it off the ceiling,and guess where the "X" will be when it hits the floor. That's how variable a signal is after it makes it around the world.That's why you have a variety of antenna types, so you can switch around as conditions require. As for the beam seeming to work better off the back, are you sure you placed the reflector and director elements correctly? If so, that too may be simply propagation.

That is sort of what makes it more puzzling. My G5RV is a flat-top, installed almost perfectly horizontal between a large tree and a telescopic mast. I am sure all the elements are in the right place on the beam.

It got even weirder last night, which is really making me start to think it's all about propagation. I was monitoring the DXpedition station in St. Barts. It was S3-S5 on the G5RV. I hooked up the beam and began rotating all around. The sweet spot was found to be facing almost due West of my location, while St. Barts is pretty much due Southwest of me. When pointing just a little bit North of West, I could get S7-S9.

I am used to my VHF beam where I point it directly at what I am trying work. I guess I just need to realize that I am dealing with a completely different beast here, and learn as I go. I found out early on as a General that propagation is the boss, not power or antennas.

What you are experiencing although perhaps curious and/or frustrating is similar to what I experience.

Here the setup is 1 dipole running North-South (East West broadside) and another dipole running East-West (North-South broadside). I am in the far Northeastern Part of the U.S. and I often get better results into Florida, VA, NC off the END of the dipole running North-South (East West broadside). Off the end, as I visualize it the "take off" angle is steeper and better for the shorter skip. The other dipole, East-West (North-South broadside), does better into places like Trinidad, & South America. This would most likely be due to the lower take off angle for the longer skip.

So, do not be discouraged. Which ever one (antenna & beam heading) is better at the moment (due to propogation) is the one to use.

My first recommendation is to look at a Buckmaster OCF dipole. These are supposed to be hung as an inverted V with the top at 30-35 feet. So you are close. But you need room for the longer 90 foot leg.

Two other thoughts... a 44 foot wire doublet (22 feet each side, balanced feed line to a balun/tuner) will cover 80 through 6 meters. Google the NorCal doublet for info on building this from speaker wire.

And a TW 2010 will gve you world class signals in a package only 8 feet tall, and ideally mounted near ground level... all without radials. The TW 2010 is an improved version of the Force 12 Sigma 5. See the reviews at EHam.net

Lastly, a Cushcraft MA5-V will give you a very nice signal in a small vertical (14 feet high), without radials, if you can mount it at near the roof line.

From: wb1fjh
Topic: 5253 Message: 5253

Hi guys,
I'm thinking about putting up a smaller sized g5rv style dipole vertically on 20 and above.I figure about 12 3/4 feet aside and fed with 300 ohm twin and run that into the 4:1 balun in the shack.
I've had good luck with g5rv/doublets fed this way horizontally ,and I wonder if any one has tried it vertically.The goal is low angle for 20dx,and running it on 10 and maybe even 6.My ldg does pretty good at fooling the rig making it see 50ohms.
Any ideas?Maybe a OCF fed with 300?
Maybe using the 16 1/2 foot aside?
Look forward to any responses,and thanks in advance.

Great thread. A couple of comments here, if I may jump in.

The prop can often depend upon the angle of arrival. Generally, directional and vertical antennas favor signals coming in from lower arrival angles, which are typically from distant locations. There are exceptions, and not all the signal may be coming from lower arrival angles (great discussion on this in ARRL Antenna Handbook). Sometimes the signal can travel via a skewed path. The exact reasons are unknown, but often directional antennas need to be turned other than directly at the receiving station (which is the advantage of the wire antennas, they are not as directional).

Personal experience with wire antennas and a 2 element wire hex beam for 20: for long distance DX (VK, Africa, and just last night working VQ9LA), the hex beam generally works perfectly on a direct shot to the receiving station.

Exception: this past winter I was hearing some South American stations on the wire better than the Hex. Higher angle of arrival was my assumption here.

Exception: I worked ZS1 on 80 meters CW on my Buckmaster wire antenna at 32 feet in height. My Cushcraft vertical for 80 could not even hear him. Conclusion? The signal was arriving at a high angle. How is this possible? Rare occurrence, but if the attenuation was minimal over the salt water path, and I got a good reflection in the middle on some of the higher angle radio waves, then it was the high angle signal which made it through. ON4UN describes skew path and high angle arrival success stories on low bands in his book.

The topic is quite fascinating, and supports a theory my Elmer told me way back when I was a youngster: when it comes to antennas, no one antenna is the answer...you always want options.

Buckmaster is definitely a good bet. There is now a shorter version for 40-6 which will probably fit on your lot. Stealthy design too. I have 2 Buckmaster antennas and I love them.

Also check out the Par EndFedz antennas. I have several of these and they are quick to install and work well and they are cheap.

Steve,

That will be an interesting experiment. It would work better on 20m and be easier to tune if it was 17 feet on each side. From what I□ve read a vertically oriented dipole will tend to interact with the ground and give you somewhat higher angle radiation if the bottom of the antenna is less than ½ wave (33 ft on 20m) up.

My guess is that it will do better than the same antenna up horizontally, but not as good as a 25 foot ground mounted vertical with lots of radials.

Everything I have read says to ground the shield through surge arrestor. If you ground the shield directly, doesn't that effectively ground the dipole element?

From: wb1fjh
Topic: 5253 Message: 5259

thanks Dick,

how i arrived at 12 3/4 ft. was a 1/4 g5rv.

i also think that it might fall into the ball park of a extended double zepp on 6 .alittle long ,but my guess is that most of the tuning in a edz is the tuned feeders.For whatever reson, people hate g5rv's.i built 2 of them.one "standard" with the matching section adn coaxiallly fed,and the other, fed with just twin.I tell people it's a vee or doublet.

I'd be interested if any of you guys are good at modeling,and it's not a pain,

to run... 12 3/4 ft. a side fed with 300, the bottom about 16 to 20 ft above average ground.

if i can beat the heat, i might just throw it together and see if she plays.the only true test.it's just motivation at this point.

If you tie the coax center and shield directly to the antenna without a balun, then one side is grounded,sure.But there are other types of arrestors that will protect the other center conductor as well.

5263. Installing Vertical - Mast in Concrete - making Sure its Plumb

Yahoo group: ham-antennas (2008)
Date: 2008-07-10 02:09:01 UTC
From: jsternmd
Topic: 5263 Message: 5263

Hi Group,

Installing my first 43' vertical and will place the 4-5' mast into a sonic tube then pour concrete. Since only a small length of the mast is above ground before concrete sets, what is the easiest method to make sure that the mast pipe is 100% vertical (Plumb) since only about 1 foot will be sticking out? I can imagine that even the smallest amount of the buried 4 feet of mast pipe being ever slightly off-plumb will lead to a tilted vertical. Any "easy" methods greatly appreciated.

Jerry,

I would put a section on the mast above ground so I had something substantial to work with to true the section in the ground.

Can you insert a longer dowel or a pipe into the base to provide an above-ground indication of plumb?

You could use the conventional methods of extending the pipe above ground and use a vertical level or a plumb bob.

OR, you could use some of the not so conventional methods.

(1) Fill it with water to the rim. When the water does not drain out to one site, it is level/plumb.

OR

(2) Wait until exactly 12:00 (Not Daylight Savings Time) on next summer's solstace (this year's is past). the sun should shine all the way down the inside to the bottom of the pipe and not cast any shaddow.

I have put up Many tall towers...
Just extend the pipe and use a Good level.
Check the level to make Sure the bubble is
true vertical. Check it on something you
think is vertical then reverse the level.

Muffler clamps come in assorted sizes. I still have one or two in the stuff I have put away.
Not a good choice for antennas, as they will rust far sooner than zinc plated U Bolts.
Hardware stores may or may not have U Bolts
A Saddle Clamp consists of a U bolt and another part, plus nuts and washers and so on.
Places like Lowe's home improvement, Home Depot and Ace hardware may have them, sold as antennas clamps. Radio shacks may or may not have them in stock.
I have bought a number of them for various antennas I have made.
It does seem to be getting harder to find them, so some searching may be in order.
YMMV

5270. 5BTV vertical

Yahoo group: ham-antennas (2008)
Date: 2008-07-10 10:27:41 UTC
From: Kurt
Topic: 5270 Message: 5270

Hello to all;

I am getting a used 5BTV in a couple of days and of course been reading up on it (I already download the manual), the reviews on eham etc.

Question for anyone who is using one.

1. In several reviews it said it was useable on 17 and 6 meters? I know Dx Eng, has a add-on trap for 17 meters, but the reviewer did not say anything about the add-on. On 6 meters how is it?

I am going to ground mount it and try to install at least 20 radials in my small yard

Thanks and 73

Jerry ,

you can make a thin plate and mount it on 4 studs with a nut on the top and bottom of the plate. This will allow you to adjust for any tilt after you concrete gets hard. Check out a picture of mine listed as 2nd tilt set up in the picture section in the Yahoo group. I hate to buy stuff if I can make it. This a tilt over mount and has a 50ft vertical on it. Really a 20m caged ½ wave vertical on a 20ft mast .

Kurt;
I have found that to be a exceptional antenna. I have mixed 225, phone 200, cw 115, 40, and 20 DXCC using the exact set up you describe (never had a beam). Have 1/2~ wave 14g thhn burried on 10,15, 20, 40, (no room for 80). 80 trap VERY hard to tune. Have added the 30 meter trap and it is very efficient. Do not know how well 17 would work. If you are in an area subject to strong winds, I do suggest guying just above the 40 mtr trap.

hi there folks

i have one of these antennas that i aquired at a second hans sale and was wondering if there was any modification i could do to the antenna so i would be able to use it on 40 & 80m i have read the specs on the website and it apears that you tune it for each opperating frequency by using the cable that is provided and plugging it into the correct sockets that run up and down the antenna that said could i not just set it as iff i was opperating on say 2020mhz or 4980mhz then use my ATU to tune it the rest of the way to work on 80m or set it to 7800mhz and again use my ATU to tune it up for 40m can anyone see an issue in doing this

While this method is sufficient for fence posts, it doesn't assure proper mixing and can alter cure rates, thus weakening the concrete. I wouldn't recommend it when the full strength of concrete is needed, such as with an antenna base.

Jerry , I would mount the lower section of the antenna or a section of steel
EMT on the base and check it with a level. You can true the assembly with
dry mix in the hole and then add water.

Subject: [ham-antennas] Installing Vertical - Mast in Concrete - making Sure
its Plumb

Hi Group,

Installing my first 43' vertical and will place the 4-5' mast into a
sonic tube then pour concrete. Since only a small length of the mast
is above ground before concrete sets, what is the easiest method to
make sure that the mast pipe is 100% vertical (Plumb) since only about
1 foot will be sticking out? I can imagine that even the smallest
amount of the buried 4 feet of mast pipe being ever slightly off-plumb
will lead to a tilted vertical. Any "easy" methods greatly appreciated.

Hi Dale, thanks for the reply. Yes and no about being in the area. I live in Allen Park, near detroit, but have a trailer at a campground in Moscow. Won't be there this weekend, but planning for next.

I am probably make it a 4btv instead of the 5 because of lack of space for radial, I should be able to put down 3 to 4 for each band if I have it figured right.

If you are on 2 meters what repeater do you listen to, maybe I will give you a shout to look at your setup.

Kurt;
I have found that to be a exceptional antenna. I have mixed 225, phone 200, cw 115, 40, and 20 DXCC using the exact set up you describe (never had a beam). Have 1/2~ wave 14g thhn burried on 10,15, 20, 40, (no room for 80). 80 trap VERY hard to tune. Have added the 30 meter trap and it is very efficient. Do not know how well 17 would work. If you are in an area subject to strong winds, I do suggest guying just above the 40 mtr trap.
Dale K9TTT
Jackson, MI
BTW; Did not look you up on QRZ, but if in the area, glad to show you set up

From: Dave
Topic: 5281 Message: 5281

Dear Group:

I have a couple of 2 element 40 meter beams that I am trying to convert to a 30 meter, 3 element beam and some of the smaller diameter aluminum rod is bent, not crimped, just bent. Anyone have any experience in straightening aluminum tubing, without crimping?

Thanks in advance.

No real good way to do it unless you alter the actual loading coils.

Yes, you very well may be able to tune it, but it will be even more of
a dummy load as far as your ERP is concerned.

From: Rich Schmuke
Topic: 5263 Message: 5283

I do have a small shop area now but the tilt up was made before I had a shop. It was made in a drive way. I had the steel sheared at the local steel supplier. My welder was in the basement and I ran the cables out the window to the driveway. The large tilt unit , one with the beam and rotor on top, did not require any welding or cutting at all . It tilts over on pivot points. I just drilled a couple of holes. The two rectangular tube part are from one piece of stock, when you buy a length , if you want it cut, the charge is $1.00 . That's cheaper than buying a saw. So no shop of your own is required to build what I have.

Jerry,

While you may only have a short piece of pipe sticking out of the wet concrete, you have the full length INSIDE the pipe to work with. Just make sure you seal the bottom end (duct tape works) so concrete does not get inside portion of the pipe in the concrete.

Then use a long level, tie a string on it incase you drop it inside the pipe, and hold it against the INSIDE of the pipe. Inside should give you the same "plumb" as outside. Finally set wheatever you are using to hold it plumb and let the concrete cure.

Keep us posted on this antenna because I, too, am considering this antenna for 80 meters.

If you have a long enough hollow pipe going into the ground, you could suspend a plumb line into it, the longer the better, and shine a bright light down the pipe. Then there's no question how good your level is.

Andy

Well, I will do my best, but if I am not clear, let me know, I am having a bit of a rough time right now my beloved wife passed on on June 26 2008, so I am having a bit of trouble phrasing things right, please forgive me.

Well for your first HF a good choice would be an off center fed dipole and with a 4:1 and a 1:1 switchable balun you might not even need a tuner with luck. You do know a tuner doesn't tune the antenna it just tunes the mismatch so the transmitter sees a 50 ohm load or there about.

Well the other choice would be a 102 ft doublet, feed with good quality twin lead, this will work fairly well from 80 to 6 and best from 80 to 10.

Place either facing mostly E/W and slightly N/S and you should be able to work a lot of DX.

multi band dipoles are nice but can be tricky to tune, and normally G5RVs are good but I find the doublet works as well if not better.

Whatever you use you will make contacts and the higher the better if you are interested in DX. Heck I have worked across town on a light bulb filament and with a tuner and 5 watts or so out on 80 CW when I was a kid. I had a guy comeback to me when I was tuning up my old Xtal controlled transmitter.

multi band dipoles are nice but can be tricky to tune, and normally G5RVs are good but I find the doublet works as well if not better.

Whatever you use you will make contacts and the higher the better if you are interested in DX. Heck I have worked across town on a light bulb filament and with a tuner and 5 watts or so out on 80 CW when I was a kid. I had a guy comeback to me when I was tuning up my old Xtal controlled transmitter.

Just something to keep in mind...
When you bury a pipe in the ground make
SURE the bottom of the pipe is in some Sand.
DO NOT close off the bottom of the pipe.

It will fill up with water then rust and Freeze
in the winter and split open..

You must make sure it can drain out.

Best of luck

Glad to have you on the air Dave , welcome aboard. Keep reading about antennas , building is a fun part of ham radio. Go to you next hamfest and pick up old antenna book, the formulas for things don't change so information on a dipole is the same in a 15 yr old book for $4 as it is in a new book for $44.

Here is a link to a little information , http://www.kc7hxc.us/links/radio/antennas.html . When you have memorized all of it try , http://www.ac6v.com/antprojects.htm. On getting on HF just cut a dipole to get on the air. Single band dipole are cheap and easy, no tuner or other parts needed. Then for maximum reach around the world a set of180 ft tower and stacked beams are great but we all cant afford that. In between those refer to the links I listed. I cant climb so I made my own tilt overs. Check out my tilt over in the picture section. Keep asking questions , you will get many answers. Keep the ones you like and put the others in your garden, they will help your plants grow.

Jerry,

I am gathering material to install (2) 48' antenna poles to raise the ends of my G5RV. I went thru this myself until I came up with my plan.
I didn't want it to be permanent so I decided to buy fence post stakes. The steel ones for the cheap wire fence with the small spade at the bottom. Pound it into the ground, you can level it very easily. After this I will take a section of schedule 80 pvc pipe with the inside diameter to just be a little larger than the antenna mast. U-bolt clamp it in a couple of places. You can put a small piece of wood to keep the pole end off of the ground. I will keep the bottom of the pvc off the ground a couple of inches so water can drain thru. Use the appropriate schedule 80 in stead of shedule 40 it has a heavier wall. Of course at 48' I will have a couple of guy rings and tied down for stability but you shouldn't need that. Good Luck with your project.
Ed Dawson

5298. 20m Hamstick Dipole

Yahoo group: ham-antennas (2008)
Date: 2008-07-11 12:23:23 UTC
From: Doug
Topic: 5298 Message: 5298

I have a hamstick dipole setup and was trying to use it for field day. It is fed with 50' RG58 connected directly to a FT100. I am using a 25' telescopic paint pole for a mast. My issue is: I was unable to use this setup due to the fact that the FT100 continuously displayed SWR when transmitting. Reception was terrific. My concern is that the dipole mounting bracket is connected directly to the paint pole which is aluminum. Does this affect the grounding and thus the SWR of the dipole? I couldn't even use my tuner to get this working.

Any ideas on my swr issue? I have heard these are a compromise which I agree with, but I also understood it that the SWR would be 2.0 or less?

Thoughts?

If you haven't already done this, for my ground mounted vertical, I sleeved PVC pipe into the base that I poured. This lets me easily lift out the vertical to take it down if I need to.

I simply stuck a piece of PVC in the hole and poured the cement around it.

I checked it with a level after I poured it and checked it a few times again for the first hour or so as the concrete began to set up.

Because it is sleeved, the vertical wobbles a bit in the sleeve, which is simply fixed by my guys, they do the final truing for me and it is a heck of a lot more stable even with just the two opposing guys I have on it now.

If one side of the antenna is connected to the mast via the bracket I would believe the aluminum mast would cause a large imbalance and high SWR.

5305. Re: bent aluminum antenna parts

Yahoo group: ham-antennas (2008)
Date: 2008-07-11 15:16:13 UTC
From: Don
Topic: 5281 Message: 5305

Hi Dave,

Actually I do have some experience in straightening
bent aluminum antenna tubing.
I had a 20 meter beam go down at field day a bunch of years ago,
and many elements were also just bent.
Figured I had nothing to loose, so I looked around for something to
use to straighten them. I ended up using the crotch in a tree.
I put the tube in the tree with the last straight section in the
crotch just at the bend and tried to move it opposite to the bend.
The darn thing started to straighten up. So I worked it a little at a
time until it was nearly back to straight again. The tube was quite
useable. Don't put too much pressure on it. Just enough to get it to
move a little then let up and try again till that part is straight.

Commercial tube straightners use a complex set of rollers set at
different angles to make tubing straight. The tube spins or turns as
it goes throught them. I have seen then in action, but do not
understand the process.

Good luck with it. Hope you can straighten them out.

Subject: [ham-antennas] New Ham

I am a new ham and looking for advice on antenns that I can build. I will be getting my general ticket as soon as I can. I was in 11 meter for 32 years and decided to move on to better things. Now I am very interested in ham radio. I made many contacts during feild day and had

a blast sure beats 11 meters. Well I guess all I need to know is how to make antennas. I made a 2 meter jpole that works great out of tv antenna wire. I need to learn more about making antennas. Hope someone can help me out Thanks Dave KB3RIP

Thanks Dale, don't be surprised if you get a call. I do not enter property unless the homeowner is home. Neighbors and Police might not understand.

Enjoy the tower when it is up. Used one for years before I was drafted at my parents(both hams and sk's now). Right now I live on a small city lot with 2 power lines(mine and neighbors going across it, so no room for a tower, and I am very careful where the vertical is going.

73 and have a great weekend
Kurt

Hi Kurt;
My number is 517.783.4761, is you are in the area. Even if I am not home you are welcome to take a peek. My info on qrz is correct. I do not even own a vhf rig, I am a DX'er and contester so all the $$ go into hf equipment, AND I am erecting my first tower in over 35 years of hamming. Lot more $$ in a tower than one would expect. (ie concrete, new hardware, etc, etc.)
Hope you do well, contact if you have questions.

To remove the "slop" between the PVC pipe and the antenna mast to
keep it from wobbling, pour some fine sand between the two.

Yeah, that's my thinking. Just wanted some verification. I'm going to put the mount on a piece of pvc to insulate from the mast and see what happens...

Thanks!

5311. Re: [ham-antennas] Best Antennas for Use in a Valley

Yahoo group: ham-antennas (2008)
Date: 2008-07-11 20:55:13 UTC
From: Wayne
Topic: 5224 Message: 5311

Sometimes the signal comes from a dirction that you might not think of.
Japan and Europe could come over the north polar region, which would be a
northerly direction rather than an easterly or westerly direction.
Even Australia could possibly come in from a southerly or northerly
direction. All depends on how the signal hops. It is often a multi hop,
bouncing off the ionosphere.
Signals do not always come from the direction you'd normally assume they
would...
One gets some strange bounces at times.
in the early 70's, we had a Florida TV station come in and take over
channel 7 out of Buffalo NY, and this was in Rochester NY. Antennas were
aimed mainly west.
Some people used to spend hour after hour trying for such hops.

For normal purposes, it is another matter...
YMMV

I have no plans but I will send you information, I have been out all day, so it will be over the weekend when I send it.

Plans for building something like this are for the mentally inhibited, I do mine all by SWAG (scientific wild ass guess) . I made up a rough print before for some one. I will find it and send it.

Glad to have you on the air Dave , welcome aboard. Keep reading about antennas , building is a fun part of ham radio. Go to you next hamfest and pick up old antenna book, the formulas for things don't change so information on a dipole is the same in a 15 yr old book for $4 as it is in a new book for $44.

Here is a link to a little information , http://www.kc7hxc.us/links/radio/antennas.html . When you have memorized all of it try , http://www.ac6v.com/antprojects.htm. On getting on HF just cut a dipole to get on the air. Single band dipole are cheap and easy, no tuner or other parts needed. Then for maximum reach around the world a set of180 ft tower and stacked beams are great but we all cant afford that. In between those refer to the links I listed. I cant climb so I made my own tilt overs. Check out my tilt over in the picture section. Keep asking questions , you will get many answers. Keep the ones you like and put the others in your garden, they will help your plants grow.

From: Tom
Topic: 5313 Message: 5317

Hi Jim, K6JMG and the Group,

The 3 turn loop is only a design.

I have never built it. Perhaps you or anyone
in the Group who would like a compact, 80 through 10
meter loop would like to build it.

I run a similar, single turn loop, shown at:
http://ph.groups.yahoo.com/group/ham-antennas/photos/view/f4ef?b=2

It has given me good results on 80 through 10 meters, but is not as compact
as the 3 turn design.

The tuner in the 1 turn loop is an ATR-30 made by MFJ. It has a 1:1 current
balun on the output of the tuner. The balun coil is wound around three, 2.5"
toroids and runs cool.

Best DX contact so far has been ZL3SV(New Zealand) on 75 meters.
ZL3SV uses a 1500' center fed sloper.

Best regards.

Dave

It depends on what type of bend it is as to how you go about straightening it.
One of the most difficult to straighten is the long curved bow that runs almost full length of the piece.
The best way I've found to straiten them is on the bed mattress.
Lay it bow up and spread both hands across as much of the length as you can and press downward. Do it a little at a time on the high point and with a little time and diligence you can get it pretty straight.
I once straightened a bowed 1/2" 0.058 wall piece like this and it was straight enough to telescope a 3/8" OD inside the full length of the 1/2" piece.

Topic: 5320 Message: 5320

Hi all
well Ive booked my CN holiday for next year and looking for a true backpacking hf antenna 80-10 if possible will have LDG Z100 atu, max 100w, this year I took a a basic 20m dipole and 8m fishing pole with cross

http://uk.ph.groups.yahoo.com/group/pmtdxgroup/photos/view/e4c4?b=8

was ok, could have done with better propagation but thats the same for everyone, but need/want to have something with better coverage. weight and size is very important, Im fully aware size matters ;)but something like a Diamond BB6W (visualy just what is needed)... this is the sort of thing for both size and coverage.any good though ?????? checked eham.....other wise a good old G5RV is light compact, I have a CW80s for trips away with poles/mast etc. But as title states BACKPACKING, psu atu radio clothes etc all in 1 rucksack and hand lugage. any thoughts ?????
regards

Mel,

Don't know if this helps any or not, but, I am switching with pretty much standard OTC 12VDC relays and not having any problems. If you take a look at the relays inside your average full power tuner you'll see they are not using anything spectacular.

As I found out two weeks ago yesterday, it is hard to believe it will get better, sudden coronary death with absolutely not warnings signs is such a shock, but it really helps to hear from some one who unfortunately has been here, Thank you and you will be in my prayers and thoughts. Btw when I do get back on the air I normally hunt the low in of 20 SSB and the low area of 40 SSB if you hear me give me a shout.

I'm 52 also- we never always know what tomorrow brings...Kinda puts life's other "problems" into real perspective. The nice part of ham radio as a life interest is you can involve yourself a lightly or heavily as you want to at the time. Then go full throddle when you're ready. We'll all be here, Kirk. Thanks for your experience added to this list.

Thanks, but I have problems with arc over on some of the smaller relays and am using the Magnecraft W199AX-14 relays and replace the wire leads with solder wick, (yes, its sounds funny, but it works great and is very flexible). Just the $20+ each is a little pricey. Yes, I am also frugal. Hi.

Mel,

Don't know if this helps any or not, but, I am switching with pretty much

standard OTC 12VDC relays and not having any problems. If you take a look

at the relays inside your average full power tuner you'll see they are not

using anything spectacular.

Hi Kirk,
I like every one else know what your going through.
I lost my Daughter in 87.
She went to work and was never seen again.
Not knowing what happened makes me think of things I really don't like to think about.
My Prayers go out to you and soon the burden will be lifted.
GOD BLESS
BOB

Also inside the relay cube, note how the wires are run from relay contacts to the base,as the wire may be coiled,looped,etc and affect tuning,add inductance,etc. I like the solder braid use as well!

I guess I'm just not sophisticated enough to worry about the amount of tuning or matching change I will get. I will let you know how this thing comes out in the finished product. I intend to tune without the switching unit in place and then put it in place and see what amount of retuning is necessary. I can also monitor the power as well. Of course my purpose may be entirely different than yours. I want to be able to switch multiple antennas to single balun to save the cost of buying multiple baluns.

One saving grace is we're working with "HF" not VHF or UHF.

Hi wayne I have not read all posts but has anybody told you about the G5IJ antenna. I use one and its tops....

Try these they work very well...

http://myweb.tiscali.co.uk/wwshack/Misc/G5IJ_aerial.htm

http://www.gairney.plus.com/Radio/G5IJ%20aerial.pdf

Hope this helps the twin feeder can be shortened or lenghtened as you wish but best to try keep in multis

Keith,

I do not know what you are going through personally but like some others I do have a clue as some years ago my wife passed away in a bad auto wreck while I was sitting right next to her there were no last words. I have recovered physically but I have never completely got past it and I believe I never will but it has become a little less painful with time.

God Bless .

Respectfully Yours,

Hi
There is a yahoo group simular to this one called griefshare It is for people who are widows and widowers only. People going thru the difficult times when their spouse passes. My wife Barbara chose on Christmas eve to have her venterlator removed rather than have a tube placed down her throat. She died on December 27,2007, just 2 months shy of 50.
You will find grief groups by that name in your local area and they help a lot. There are many others sponsered by many different groups. I hope that this helps a little.

5337. Antenna Tuning Problems

Yahoo group: ham-antennas (2008)
Date: 2008-07-14 04:04:16 UTC
From: adkscan
Topic: 5337 Message: 5337

Is there any reason why a TS-2000 would all of the sudden not tune a G5RV on 20M when it usually tunes on 20M with no problem?

I have the TS-2000 with 25' of RG-8/U running to a G5RV mounted in a slightly inverted V at about 35ft above ground along a line of pine trees.

I can tune every other band like I usually do except for 20M. With the TS-2000s internal tuner I can tune 160M, 80M, 40M, 30M, 17M, 15M, and 12M. For some reason sometimes I can tune 10M and 6M also.

I have never had a problem tuning 20M until today. The only contributing factor that I can think of is the weather. We have had about 2" of rain in the last 24 hours. Could the wet wires touching the wet pine needles cause problems with SWR on 20M only?

Any help would be appreciated

Thanks,
Mike -- KC2TOH

Thanks, and sharing your story with me helped a bit also, I will look into grief share. I live so far out in the country my priest and friends are looking at starting one for people like me, but there are no existing groups close. I will look into I didn't mean to get a thread started, I mentioned what had happened in a response to a question and people wrote back, I was so upset I didn't know if I made sense so I explained why. Your kind response and advice has helped at least I don't feel so a lone and if no one can understand how much it hurts and how bad I miss her. I hope that the tranq I am taking that my doc prescribed will help in a few also.

Well I don't think it is the TS-2000 now. The sun is out this morning and all the pine trees and the antenna is dried off. And what do you know, the G5RV now tunes on 20M! So I guess it was the rain interaction between the G5RV and the pine trees. Everything seems to be working fine now. I guess I have to try to get the G5RV away from the pine trees, which will be almost impossible.

Mike,
Water on the 300 or 450 line really affects the antenna
Since it's non sheilded and full of RF I'd say that was your problem

5341. [ham-antennas] Mobile antenna question

Yahoo group: ham-antennas (2008)
Date: 2008-07-14 15:46:42 UTC
From: J. Harrell
Topic: 5341 Message: 5341

Hello, I have been looking at ham sticks for some time now. I have a question. I have 2 four foot fiberglass rods that are wound with wire currently for the 11 meter band, would it be possible to unwind the wire that is currently on the fiberglass rod and rewind one of the rods for the 80 meter band and the other for the 40 meter band? I don't know how much wire to wind on the rod to make it work on these bands? With the ham stick antennas are they based on 1\4 wavelength? Any instructions on making your own laying around? Also would anyone know where I can buy a complete set of ham sticks for all the bands, that way I could just pick the band and screw on the correct stick and go for my mobile? Also any one used the OPEK HVT-400 multiband antenna? I was looking at one of these to use for portable ops as well as on my mobile.

Thanks,
Joey

The box provides a match and capacitive coupling through the glass to the antenna. The screw is for adjusting the coupling to get a minimum SWR. You need a SWR meter or antenna analyzer to adjust it.

There are a few different manufactures. Larsen is one as is Radio Shack.

Hi Joey,

The direct answer is yes. Is it worth it? Not in my opinion. By the time you buy the wire, rewind the rod, solder the end, getting the coil winding right, etc. As far as buying all the hamsticks any ham store should sell them. Universal Radio or Ham Radio Outlet is just two. One note all bands can run you over $200.00.

5346. Re: [ham-antennas] Mobile antenna question

Yahoo group: ham-antennas (2008)
Date: 2008-07-14 16:33:38 UTC
From: Leonard K. Pennock
Topic: 5341 Message: 5346

You could rewind them but the hard part is figuring out the winding you need. There is a set of plans on the net to rewind a fiberglass CB antenna into a outbacker style (HVT-400B) multiband antenna; however, I don't have the link to send you.

Universal radio use to sell a set of 5 hamstick but looking at their site it appears to be discontinued. Personally I would recommend just getting a couple and be done with it for now. 75/40/20 is all I carry anymore as at this point in the sun spot cycle above 20 is dead most of the time.

You may want to look at the Quick disconnect sets for your antenna. Cheapham sells the OPEK KD-5 set which allows you to quickly switch antennas with a 1/4 turn of the antenna.

If you don't have the problem due to a tree branch at just the right point wash your ladder line off and it will often solve that trouble a lot of the crud that builds up on ladder line over time is conductive and causes unbalanced feed and capacitive and inductance problems, I was mine off about once every 6 months on my ladder line antennas.

In the past I always applied a good quality (make sure it wont attack the PVC) paste floor wax to commercial "ladder line". Seemed to reduce the affect of moisture.

Now I use homebrew made from insulated house wire and spreaders from plastic coat hangers. No longer have the problem of moisture, wind, etc. Same transmission line has been up 20 or so years.

Troy, W6HV

Could you apply some type of maybe automotive wax to the plastic 450 ohm wire? May allow moisture to be repelled.

I suggest you lower the antenna near the tree and inspect the wire for spots that would be burned black. If using uninsulated wire look more closely.

You can certainly feed a 9' whip with the proper tuner -- something like the Icom AH-4 would work. The tuner needs to be designed for random-wire operation -- a regular built-in tuner like some HF rigs have generally doesn't have a wide enough range of impedance that it can match.

But don't expect a 9-foot whip to work very well at all below about 14 MHz. I've tried it, and they work OK for 6-20 meters, but when you get on 40 meters, they work -- sort of -- but on 60 and 75 meters, forget it. Your signal just isn't going to be strong enough to use. I believe the ERP on 75 meters is on the order of 1 or 2 watts in this case.

As for the dipole idea -- seems I've seen an 18-wheeler somewhere like that, but I don't know how well it worked.

BTW, I'm the new guy on this mailing list.

They may be inefficient compared to a full size antenna but they still
work. Some just work better than others. My hamsticks work better than
my UHV-6 but not my much.

Thanks for the link, I will try to contact him and go from there. If I decide to go with a set of ham sticks it will be better than nothing, I just don't $400 to invest in a screwdriver antenna at the moment. Im sort of in a money crunch and going through college as well so money is tight and gas prices hasn't helped any.

Thanks,

Joey

Subject: [ham-antennas] Matching 75ohm to 50ohm

Dear Group

I have searched the archives but found no suggestions on this one... does anyone have any ideas for matching 75ohm coax to the 50ohm connection on the transceiver?

As I work in the cable industry, I have a plentiful supply of low-loss 75ohm coax and am using it to feed various dipoles (inherently 75-ohm impedence in any case). I don't seem to be able to find any instructions for a suitable "un-un" (other than single frequency stubs).

Any suggestions welcome.

Doesn't this impedence seen at the txvr input vary according with the frequencies? Another words, you may see 50 ohms at 80 meters, but more or less at maybe 20 meters. So, how does one stablize a moving target?

5369. Workman coax switches

Yahoo group: ham-antennas (2008)
Date: 2008-07-19 15:29:55 UTC
From: Kenny Wyss
Topic: 5369 Message: 5369

Does anyone have any experience with the Workman switches? There are a ton of people selling these things on ebay and they are about half the price of the MFJ switches or less. I contacted one of the sellers and Workman themselves, but no one seems to know the insertion loss on these things. I don't want to put a switch inline that is going to cause me to lose a couple of dBs.

We have a big hamfest nearby tomorrow, so I will be keeping my eyes open for some decent switches.

Kenny, KB0NPW

My personal opinion: pretty flimsy.
Very light-duty switch with hook-up wire to connectors,
randomly crammed in housing would give unpredictable
capacitance/inductance properties.
Bought one, opened it to inspect workmanship (poor), put it back
together and tossed it in my "miscellaneous" box.
IMHO: Stick with MFJ or similar with formed "bus-bar" wiring.

5372. The 2008 CQ World-Wide VHF Contest

Yahoo group: ham-antennas (2008)
Date: 2008-07-19 17:14:19 UTC
From: James
Topic: 5372 Message: 5372

I am getting slow in my old age. I almost forgot all about it. Starts in 45 min as of this email post.

Announcing:
The 2008 CQ World-WideVHF Contest
Starts: 1800 UTC Saturday, July 19, 2008

Ends: 2100 UTC Sunday, July 20, 2008

I just spent the past 6 hours mounting and fine tuning the 5 element 6M beam antenna on the roof, lubing up the rotor since it hasn't moved in 4 years and tying off ropes because the tripod is just standing on top of the house not bolted down.

I hope there is no wind today, the power lines are not friendly!

Subject: Re: [ham-antennas] Workman coax switches

My personal opinion: pretty flimsy.
Very light-duty switch with hook-up wire to connectors,
randomly crammed in housing would give unpredictable
capacitance/inductance properties.
Bought one, opened it to inspect workmanship (poor), put it back
together and tossed it in my "miscellaneous" box.
IMHO: Stick with MFJ or similar with formed "bus-bar" wiring.

I appreciate the inside info. A friend purchased two of their big 2m/70cm vertical antennas which are basically copycats of my Diamond X510NA, and they perform beautifully. I can recommend those.

Does anybody have a couple of hoods (Amphenol Part# 083-765 or similar)for
SO-239 connectors they'd be willing to part with. I only
need 2 and don't want to gin up an order just for that.

Mike , do you need them for RG-58 or RG-8X , I should have both kinds in my shack.

Gee, they are for coax and that's a part of the antenna system so its not off topic.

I'm going to use it with RG-142B/U, which is the size of -8X I think. But. I think I might have it covered. Not too much stuff uses the hoods anymore, but I need them for inside my repeater.

Well I checked into what you want and what I have is different. You need the 4 hole mount , I use the MX-539/U screw mount. When I make up and J-Pole or other antenna for people I run enough RG-8X to get the in the clear and enough it they need a few turns for a choke. I terminate this coax with a hood and a single hole chassis mount SO-239 . This can be sealed with a little RTV and shrink. Then when mounted the person can run the coax of their choice with a PL-259 on the end and not need two ,259's and a 258.

I am getting slow in my old age. I almost forgot all about it. Starts in 45 min as of this email post.

Announcing:
The 2008 CQ World-WideVHF Contest
Starts: 1800 UTC Saturday, July 19, 2008

Ends: 2100 UTC Sunday, July 20, 2008

I just spent the past 6 hours mounting and fine tuning the 5 element 6M beam antenna on the roof, lubing up the rotor since it hasn't moved in 4 years and tying off ropes because the tripod is just standing on top of the house not bolted down.

I hope there is no wind today, the power lines are not friendly!

I have had 146.520 on all weekend and never heard a peep. 6M was the pits for this area. Was watching the DX clusters and my surrounding grids rarely show up. I watched in the maps and skips that were always going over us, never making a landing. 1 Tropo and 1 Backscatter. I made 5 contacts total.. Not a good weekend for 6 around here.

5384. An update on my vertical G5RV

Yahoo group: ham-antennas (2008)
Date: 2008-07-21 03:42:37 UTC
From: wb1fjh
Topic: 5384 Message: 5384

Hi guys,
Earlier,I posted I was going to play around with a vertical g5rv for
20-6.
Well,it worked,but not quite as well as I had hoped.
So I changed it over to a vertical off center fed dipole.
It seems to work pretty well on 20.
I am not sure how much was propagation, and how much was the
vertical "seeing" above the horizom,but I managed to work several Dx
stations and broke a few pile ups with my little Ft 450's 100 watts.
I chose the OCF because I was feeding it with 300 twin.
I fed it at 66.7% on the 1/2 wave.
The other bands wer'nt open so I can't give any input there.
On 6,an interesting thing happened.
My auto tuner tuned it fine,but at 1:1 the performance went down.
At about 1:7 it worked,but not great.
I guess the tuner was absorbing all the Rf on 6.
But,on 20,the vertical ocf kicked butt on my loop which the apex is
45ft and the bottom is about 16ft off the ground.
If anyone cares,there you go.
Alot easier than a bunch of radials.
73

5385. coax to balun connection

Yahoo group: ham-antennas (2008)
Date: 2008-07-22 00:21:52 UTC
From: Renze VE6DC
Topic: 5385 Message: 5385

Hi everybody,

Within the next couple of weeks I hope to have my (new to me) tower up with a new tribander yagi (20, 17 and 15). This antenna came with a 2:1 current balun. On the balun is a so239 chassis connector and of course I have to solder a pl 59 at the end of the coax for the connection.

But I was wondering, since this is another connection with a possible (small) loss, would it benificial to just skip these 2 connectors and solder the coax directly to the balun.

I realize it would come with new problems like how to disconnect and I would have to make it weatherproof some other way but for now I am wondering if the loss would less.

I would appreciate comments and suggestions.

Regards, Renze VE6DC

5386. Re: coax to balun connection

From: billncolo36
Topic: 5385 Message: 5386

I would take the time and use the connectors. From a practical standpoint, you probably wouldn't see any difference with regards to loss initially. I would be surprised if the loss thru a properly assembled PL-259 connection is more than 0.1 dB at 30 MHz. On the otherhand, when you disturb the 50 ohm impedance by wiring the coax directly to the balun, you create a VSWR mismatch that wouldn't have been there if you had used the connectors. Again, not a big deal at 30 MHz (probably less than 0.1 dB). The main issue for me is the weather proofing of the connection. I would expect that you will have to do a lot more to try and seal a non-connectorized interface, and in my opinion, you probably won't be successful due to the constant movement of the coax-balun juntion. The corrosion eventually caused by the water getting into the coax over time could easily add 0.5 dB of loss to the connection.

5387. A-Frame Tower/Mast Construction

Yahoo group: ham-antennas (2008)
Date: 2008-07-22 19:26:49 UTC
From: denisnh
Topic: 5387 Message: 5387

Hi All. I'm in the process of moving to a new location and all my books are packed away. I remember reading in at least one of my antenna books about the construction of an A-Frame (tower or mast?).

I've been asked by a friend if I have any idea how to build one and while I can probably improvise one myself, I'd rather go by an established and tested building method. I've searched the internet and found nothing on the A-Frame. The article I read a year or two ago was very complete and detailed. I sure could use it now!

Are there any web sites or easily obtainable sources of information for building the A-Frame? I would like to make it as high as possible, while remaining practical and safe, so basically the sky is the limit. :)

I would be grateful for any information you can offer.

Thanks!
Denis

Hey everyone,

I know this is totally off topic. I know no one on these lists knows me. This isn't a spam email. My mother passed away on June 18, 2008 after a 16 month battle with ALS or what some call Lou Gehrigs Disease. I'm trying to raise donations for MDA in memory of my mom, Nora Williams. Included is a link to my MDA sponsored web site which shows a picture of my mom holding my little boy shortly after his birth 2 years ago. I'm in the background with my back to the camera. Any donation is tax deductible and can be done directly through MDA's web site so it doesn't involve any money going to me. Please feel free to send this on to as many people as you want. I'm currently not receiving email on some of these lists so feel free to email me directly if you need any further info.

5391. A Home brew antenna story...

Yahoo group: ham-antennas (2008)
Date: 2008-07-23 12:41:05 UTC
From: Leo
Topic: 5391 Message: 5391

Hello Group,
A few days ago my brother and I picked up an old Rohn tower from a relative. They told me there was an antenna in one of their sheds. They said they thought it was the antenna that my late father and I made for my use when I became a Novice in 1959.

I retrived the antenna and it was the very same one I used in 1959. It was amazing that they got it from my father when I left the farm and saved it for nearly 50 years.

I plan to clean it up and restore it. I would very much like to restore it to it's original condition. The antenna was constructed from plans shown in the 1959 "The Radio Amateur's Handbook".

I am looking for the stand-off insulators shown in the photos that I uploaded in album labeled "lcr_retired K9RSO". I have located insulators that will work but having the original type would be great.

I will upload photos after it is restored. I tested the SWR in the position shown in the first photo. The SWR was 1.2 over the 15 meter CW band.

73, Leo K9RSO

What a great story And I'll be looking for you on the air with it. I have an antenna story as well but not quite like yours. I am new to HF and built a quick down and dirty G5RV-Jr antenna to get me on the air, it has worked Ok and I've made a number of contacts. IN the meantime I have built a full G5RV with proper twin lead, balun etc now I have what I can only call antenna-itis (some might just call it being a ham.) My new antenna lets me hear far off rare DX but not always work it, I'm thinking I need a tower and beam now hihi

5393. RFI in the shack with Alpha-Delta DX-LB Plus

Yahoo group: ham-antennas (2008)
Date: 2008-07-23 15:47:51 UTC
From: Darryl Wagoner
Topic: 5393 Message: 5393

Greetings,

I just picked up an Alpha-Delta DX-LB Plus dipole. This dipole is a coax center feed.

Based upon information from http://www.k8dns.com/balun.html I created a RF air core choke with an 8" sonan(sp) tube and wrapped about 15 feet around it or about 8 turns.

It cleared up the RFI problem that was causing my T1 Internet line to crash, but now I have 2 new problems:

1. It is deaf on 20 and above and not great on 80 & 40.
2. Tunning range is very short, maybe 25-50 kc and I have to retune.

One guess I have is the choke is too close to the dipole.

Suggestions? Ideas?

thanks and 73

While I don't know the antenna you mentioned, may it just be that it's working more like should?

Adding that choke removed the feed line from being part of "the" antenna as witnessed by your T1 not being RFI'd anymore.

Just for chuckles, try moving the balun loser to the shack, that way you might be able to reintroduce some of the shield back into functioning as part of the antenna while still keeping the rf from getting to the T1 line. I know, it sounds a bit like witchcraft, but isn't that what being a ham is about? Messing around with something till it works the way we want? Or until we learn, "that it just ain't gonna work that way".

Just a thought, or two.

Hello all,

I have been looking at the LB with great interest, but as I understand:

1) it is a tuned dipole
2) It is designed for 160, 80 and 40 meters, not 20 m.
3) Since it is a shortened dipole, the bandwidth ought to be narrow.
4) Since it is coax fed, the shield should not be part of the antenna.

Please tell me if I misunderstand this antenna design.

BTW, My 102 ft G5RV crashes my Internet Wireless router when I operate on 160 meters. It was not meant to operate on 160. It is half the length of the 160 m version of G5RV.

Hi Dan,
The DXLB is a shortened dipole for 160, 80, 40M and does have a higher "Q" and thus a narrower BW than full length dipoles. Typical 2:1 SWR BW is 160M/20Khz, 80M/50 Khz and 40M/75Khz and, of course, this varies with installation and site. The various elements starting with 40M may be tuned (length adjusted) to center the <2:1 SWR segment on your preferred operating range and, of course, a tuner, either wide range outboard or 3:1 built-in, may be used to increase the usable BW. Any convenient 1:1 balun or current choke such as 8 turns X 8" of the coax can be used effectively to decouple the feedline from the antenna if this is deemed necessary (not always required but never a bad idea). For coverage of 20, 15 and 10M there is the DX-LB Plus; same as the DX-LB but with two (2) underslung elements to cover these additional bands.

Hello all,

I have been looking at the LB with great interest, but as I understand:

4) Since it is coax fed, the shield should not be part of the antenna.

Please tell me if I misunderstand this antenna design.

Dan, in item 4 'should' is the more correct term. It has been proven that some of the rf will travel down the outside of the coax shield. That's why there are such devices as baluns.
The addition of the balun chokes off the rf on the shield's outside removing it from the total antenna. It sounds like you were running a kind of flat top antenna, an antenna who's radiated pattern includes both horizontally and vertically polarized waves. see: Inverted "L" antennas.
The length of the feed line will determine the total pattern of the antenna just as will the orientation of the dipole elememts. It will also determine the level of "rf in the shack". Also, the orientation of the feeder will have some effect with the least amount of rf being induced onto the shield if the feeder comes to the antenna at right angles.

Stan

Jim

Sounds like you are technically savvy on this antenna. I read a post where a ham had problems with the DX-LB and when he removed the arc plug, it worked great. Any comments on this?

Also, are those loading coils or traps on this antenna? If loading coils, how do they make the antenna resonate on 40 and 80 without trap capacitors?

I'm not aware of a problem: if the operating temperature range for the insulation is equivaent the only other thing is abrasion resistance (not really relevant in a wound balun anyway). I would be happy to use Tefzel or similar.

If the static plug has blown the antenna will not function since it shorts both sides together. Also if you operate at high SWR using a tuner you need to remove the plug as that will blow it.

They use stray capacitance in the coils to form a trap circuit, hence, they have no caps but are still a trap.

Thanks. When I buy one of these, I will immediately remove the arc / static plug. I use a tuner and I don't want to lower the antenna in teh middle of a pileup or contest to remove the plug if it shorts in teh heat of battle.

If the static plug has blown the antenna will not function since it shorts both sides together. Also if you operate at high SWR using a tuner you need to remove the plug as that will blow it.

They use stray capacitance in the coils to form a trap circuit, hence, they have no caps but are still a trap.

Hi Stan and the group,

No, before I put the RF Choke on it was working almost as good as my beam on 20 meters. I was surprized on how well it did work. I was a happy camper until the COOP members started to call to say the Internet was down.

Do I know the problem is either the choke or the cable. From the responses from Dan and others I think it is the cable.
Of all the dipoles I have run, this one worked the best!

I have an Ameritron 811H which push about 500-550 Watts CW.
What size of coax do I need?

thanks & 73

When I need to feed a dipole from 50 Ohm coax I attach quarter wave coaxial cable section (so-called Pawsey stub) to make my feed balanced. This is common knowledge, works great, described in every antenna book.

Now I need to feed dual band dipole from 50 Ohm coax and bandwidth of Pawsey stub balun is much too narrow to cover both bands. If I attach two Pawsey stubs, one per each band, will I get dual band balun?

The primary reason for using teflon insulation in smallish baluns is
because of the heat resistance. When you solder the wires in a balun,
the heat travels rapidly up into the balun core, where visual
inspection is exceptionally difficult to accomplish. Thus, the use of
teflon insulation, which expands but does not melt away when heated,
makes for less possibility of an un-inspectable short circuit.

If the TefzelR ETFE wire has the same characteristics, then you'd be
fine to use it.

Yes. Both sections only look a quartewave long at the design frequency and hence the transforming action you require (unbalanced to balanced) is achieved at those two discrete frequencies where the length is a quarter of a wavelength .

From: jim burns
Topic: 5393 Message: 5410

Hi Dan,
Yes, I know a little about this antenna as I have worked for Alpha Delta for 15 years now. I'm sorry if my response sounded like an advertisement; it wasn't meant to be.
The SEP cartridge which is located in the center insulator contains a gas tube which will drain off a static charge once it reaches a critical level. Also, it could be argued that the device provides some degree of protection from lightning induced surges although since there is a relatively long path to ground through the coax shield and since that ground may be your radio's chassis, lightning protection should be provided nearer to a heavy grounded point such as at the point where the coax enters the shack. The problem sometimes encountered with the SEP is that many hams use tuners to feed the antenna and thus get power into the antenna at relatively high SWR's at the feedpoint. If you can tolerate the feedline losses at these elevated SWR levels all is OK unless the high SWR causes the RF voltage at the feedpoint to exceed the breakdown voltage of the SEP cartridge which is 1KVDC. At transciever power levels (100W - 200W) this is not a problem even with moderate SWR but, as power and SWR increase, the gas tube can go into conduction which produces a "short" at the antenna feedpoint. This, of course, isn't good but the tube quinches as soon as the power is removed. This sometimes happens only on modulation peaks. Since the DXLB and DXLB+ cover 160M with a narrow 2:1 bandwidth (typically 20 KHz) most operators are using a tuner to get some extra bandwidth. Considering that the SEP was being driven into conduction quite often on the DXLB and DXLB+ due to a combination of power and SWR from the use of tuners, the LB series is no longer shipped from the factory with the SEP installed. It's an easy job to remove the SEP on earlier models but there is no reason to do so at moderate power and SWR levels where the problem has not been observed.
Regarding the inductors as to whether they are loading coils or traps, the answer is simple, they are both. The inductors act as loading coils to make an electrically short section of wire resonate at the desired frequency. Also, at another range of frequencies, for instance 7 MHz to 7.3 MHz (40M trap, 80M/160M loading coil), they act as traps, actually resonating with the distributed capactance of the inductor's windings. No trap capacitor to blow !
I hope this explanation is helpful and I apologize for being "longwinded".

Subject: Re: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Hi Dan,
The DXLB is a shortened dipole for 160, 80, 40M and does have a higher "Q" and thus a narrower BW than full length dipoles. Typical 2:1 SWR BW is 160M/20Khz, 80M/50 Khz and 40M/75Khz and, of course, this varies with installation and site. The various elements starting with 40M may be tuned (length adjusted) to center the <2:1 SWR segment on your preferred operating range and, of course, a tuner, either wide range outboard or 3:1 built-in, may be used to increase the usable BW. Any convenient 1:1 balun or current choke such as 8 turns X 8" of the coax can be used effectively to decouple the feedline from the antenna if this is deemed necessary (not always required but never a bad idea). For coverage of 20, 15 and 10M there is the DX-LB Plus; same as the DX-LB but with two (2) underslung elements to cover these additional bands.

Subject: Re: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Hello all,

I have been looking at the LB with great interest, but as I understand:

1) it is a tuned dipole
2) It is designed for 160, 80 and 40 meters, not 20 m.
3) Since it is a shortened dipole, the bandwidth ought to be narrow.
4) Since it is coax fed, the shield should not be part of the antenna.

Please tell me if I misunderstand this antenna design.

BTW, My 102 ft G5RV crashes my Internet Wireless router when I operate on 160 meters. It was not meant to operate on 160. It is half the length of the 160 m version of G5RV.

While I don't know the antenna you mentioned, may it just be that it's working more like should?

Adding that choke removed the feed line from being part of "the" antenna as witnessed by your T1 not being RFI'd anymore.

Just for chuckles, try moving the balun loser to the shack, that way you might be able to reintroduce some of the shield back into functioning as part of the antenna while still keeping the rf from getting to the T1 line. I know, it sounds a bit like witchcraft, but isn't that what being a ham is about? Messing around with something till it works the way we want? Or until we learn, "that it just ain't gonna work that way".

Just a thought, or two.

Stan

Subject: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Greetings,

I just picked up an Alpha-Delta DX-LB Plus dipole. This dipole is a
coax center feed.

Based upon information from http://www.k8dns.com/balun.html I created
a RF air core choke with an 8" sonan(sp) tube and wrapped about 15 feet
around it or about 8 turns.

It cleared up the RFI problem that was causing my T1 Internet line to
crash, but now I have 2 new problems:

1. It is deaf on 20 and above and not great on 80 & 40.
2. Tunning range is very short, maybe 25-50 kc and I have to retune.

One guess I have is the choke is too close to the dipole.

Suggestions? Ideas?

thanks and 73

Jim

Thanks for the info.

Presently I use the 102 ft G5RV on 80 and 160. Too short for 160 but it works well enuf to get a clean sweep on VP6DX. The short lengtrh on 160 means a lot of tuner adjustements. I also use teh G5RV on 60 meters with the tuner.

My plan is to use the DXLB on 160, 80 and 60 meters. I plan to use a tuner again on teh LB and am hoping that it will perform equally well on 60 as the G5RV does. (Worled AH2L on teh g5rv on 60 m.

The G5RV is mounted as inverted V 30 ft at teh apex. Plan is same for the LB. Do you see any problems with this arrangement? I want to use the MFJ auto tuner on the LB and eliminate the manual Versa Tuner completely. The MFJ auto tuner is supposed to be able to handle a huge range of impedance up to 3200 ohms.

When operating at high antenna SWR the voltages that can be produced can exceed the break down voltage of capsule. The tuner allows the radio to deliver full power when the antenna SWR is high.

Rich,

In fact many toroid balun designs specify Teflon sleeving over solid wire. One, for the
correct impedance, and two, for the higher breakdown voltage.

Subject: [ham-antennas] Wire

I often see a note about the use of Teflon wire for baluns . Does any know a reason why TefzelR ETFE insulated wire would not be as good or better because the dielectric strength is even higher and the main reason it I have some wire on hand. Ref wire type M22759/16 (12ga)

Subject: Re: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Jim

Thanks for the info.

Presently I use the 102 ft G5RV on 80 and 160. Too short for 160 but it works well enuf to get a clean sweep on VP6DX. The short lengtrh on 160 means a lot of tuner adjustements. I also use teh G5RV on 60 meters with the tuner.

My plan is to use the DXLB on 160, 80 and 60 meters. I plan to use a tuner again on teh LB and am hoping that it will perform equally well on 60 as the G5RV does. (Worled AH2L on teh g5rv on 60 m.

The G5RV is mounted as inverted V 30 ft at teh apex. Plan is same for the LB. Do you see any problems with this arrangement? I want to use the MFJ auto tuner on the LB and eliminate the manual Versa Tuner completely. The MFJ auto tuner is supposed to be able to handle a huge range of impedance up to 3200 ohms.

Subject: Re: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Hi Dan,
Yes, I know a little about this antenna as I have worked for Alpha Delta for 15 years now.
I'm sorry if my response sounded like an advertisement; it wasn't meant to be.
The SEP cartridge which is located in the center insulator contains a gas tube which will

drain off a static charge once it reaches a critical level. Also, it could be argued that the device provides some degree of protection from lightning induced surges although since there is a relatively long path to ground through the coax shield and since that ground may be your radio's chassis, lightning protection should be provided nearer to a heavy grounded point such as at the point where the coax enters the shack. The problem sometimes encountered with the SEP is that many hams use tuners to feed the antenna and thus get power into the antenna at relatively high SWR's at the feedpoint. If you can tolerate the feedline losses at these elevated SWR levels all is OK unless the high SWR causes the RF voltage at the feedpoint to exceed the breakdown voltage of the SEP cartridge which is 1KVDC. At transciever power levels (100W - 200W) this is not a problem even with moderate SWR but, as power and SWR increase, the gas tube can go into conduction which produces a "short" at the antenna feedpoint. This, of course, isn't good but the tube quinches as soon as the power is removed. This sometimes happens only on modulation peaks. Since the DXLB and DXLB+ cover 160M with a narrow 2:1 bandwidth (typically 20 KHz) most operators are using a tuner to get some extra bandwidth. Considering that the SEP was being driven into conduction quite often on the DXLB and DXLB+ due to a combination of power and SWR from the use of tuners, the LB series is no longer shipped from the factory with the SEP installed. It's an easy job to remove the SEP on earlier models but there is no reason to do so at moderate power and SWR levels where the problem has not been observed.
Regarding the inductors as to whether they are loading coils or traps, the answer is simple, they are both. The inductors act as loading coils to make an electrically short section of wire resonate at the desired frequency. Also, at another range of frequencies, for instance 7 MHz to 7.3 MHz (40M trap, 80M/160M loading coil), they act as traps, actually resonating with the distributed capactance of the inductor's windings. No trap capacitor to blow !
I hope this explanation is helpful and I apologize for being "longwinded".

Subject: Re: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Hi Dan,
The DXLB is a shortened dipole for 160, 80, 40M and does have a higher "Q" and thus a narrower BW than full length dipoles. Typical 2:1 SWR BW is 160M/20Khz, 80M/50 Khz and 40M/75Khz and, of course, this varies with installation and site. The various elements starting with 40M may be tuned (length adjusted) to center the <2:1 SWR segment on your preferred operating range and, of course, a tuner, either wide range outboard or 3:1 built-in, may be used to increase the usable BW. Any convenient 1:1 balun or current choke such as 8 turns X 8" of the coax can be used effectively to decouple the feedline from the antenna if this is deemed necessary (not always required but never a bad idea). For coverage of 20, 15 and 10M there is the DX-LB Plus; same as the DX-LB but with two (2) underslung elements to cover these additional bands.

Subject: Re: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Hello all,

I have been looking at the LB with great interest, but as I understand:

1) it is a tuned dipole
2) It is designed for 160, 80 and 40 meters, not 20 m.
3) Since it is a shortened dipole, the bandwidth ought to be narrow.
4) Since it is coax fed, the shield should not be part of the antenna.

Please tell me if I misunderstand this antenna design.

BTW, My 102 ft G5RV crashes my Internet Wireless router when I operate on 160 meters. It was not meant to operate on 160. It is half the length of the 160 m version of G5RV.

While I don't know the antenna you mentioned, may it just be that it's working more like should?

Adding that choke removed the feed line from being part of "the" antenna as witnessed by your T1 not being RFI'd anymore.

Just for chuckles, try moving the balun loser to the shack, that way you might be able to reintroduce some of the shield back into functioning as part of the antenna while still keeping the rf from getting to the T1 line. I know, it sounds a bit like witchcraft, but isn't that what being a ham is about? Messing around with something till it works the way we want? Or until we learn, "that it just ain't gonna work that way".

Just a thought, or two.

Stan

Subject: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Greetings,

I just picked up an Alpha-Delta DX-LB Plus dipole. This dipole is a coax center feed.

Based upon information from http://www.k8dns.com/balun.html I created a RF air core choke with an 8" sonan(sp) tube and wrapped about 15 feet around it or about 8 turns.

It cleared up the RFI problem that was causing my T1 Internet line to crash, but now I have 2 new problems:

1. It is deaf on 20 and above and not great on 80 & 40.
2. Tunning range is very short, maybe 25-50 kc and I have to retune.

One guess I have is the choke is too close to the dipole.

Suggestions? Ideas?

thanks and 73

Hi Dan,
The DXLB is a shortened dipole for 160, 80, 40M and does have a higher "Q" and thus a narrower BW than full length dipoles. Typical 2:1 SWR BW is 160M/20Khz, 80M/50 Khz and 40M/75Khz and, of course, this varies with installation and site. The various elements starting with 40M may be tuned (length adjusted) to center the <2:1 SWR segment on your preferred operating range and, of course, a tuner, either wide range outboard or 3:1 built-in, may be used to increase the usable BW. Any convenient 1:1 balun or current choke such as 8 turns X 8" of the coax can be used effectively to decouple the feedline from the antenna if this is deemed necessary (not always required but never a bad idea). For coverage of 20, 15 and 10M there is the DX-LB Plus; same as the DX-LB but with two (2) underslung elements to cover these additional bands.
Jim, WB4ILP

Hello all,

I have been looking at the LB with great interest, but as I understand:

1) it is a tuned dipole
2) It is designed for 160, 80 and 40 meters, not 20 m.
3) Since it is a shortened dipole, the bandwidth ought to be narrow.
4) Since it is coax fed, the shield should not be part of the antenna.

Please tell me if I misunderstand this antenna design.

BTW, My 102 ft G5RV crashes my Internet Wireless router when I operate on 160 meters. It was not meant to operate on 160. It is half the length of the 160 m version of G5RV.

While I don't know the antenna you mentioned, may it just be that it's working more like should?

Adding that choke removed the feed line from being part of "the" antenna as witnessed by your T1 not being RFI'd anymore.

Just for chuckles, try moving the balun loser to the shack, that way you might be able to reintroduce some of the shield back into functioning as part of the antenna while still keeping the rf from getting to the T1 line. I know, it sounds a bit like witchcraft, but isn't that what being a ham is about? Messing around with something till it works the way we want? Or until we learn, "that it just ain't gonna work that way".

Just a thought, or two.

Stan

Subject: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Greetings,

I just picked up an Alpha-Delta DX-LB Plus dipole. This dipole is a
coax center feed.

Based upon information from http://www.k8dns.com/balun.html I created a RF air core choke with an 8" sonan(sp) tube and wrapped about 15 feet around it or about 8 turns.

It cleared up the RFI problem that was causing my T1 Internet line to crash, but now I have 2 new problems:

1. It is deaf on 20 and above and not great on 80 & 40.
2. Tunning range is very short, maybe 25-50 kc and I have to retune.

One guess I have is the choke is too close to the dipole.

Suggestions? Ideas?

thanks and 73

From: Darryl Wagoner
Topic: 5417 Message: 5418

I don't know about the DX-EE, but I was amazed at how well my DX-LB+ did when I got it. I had a Van Gordon all bander which didn't perform 1/4 as well. This may have been due to the window line running too near metal or other stuff. Which is one of the reasons I switched to Alpha-Delta. I wanted to get away from the window line. Window/ladder line seems too much like black magic to me.

When I went to HRO to buy my amp and dipole, my intent was to get a B&W folding dipole. I guess B&W no longer sales thur HRO and one of the sales people there had high praise for A/D dipoles. I think he had a DX-EE and was working QRP DX. This was my first Alpha-Delta produce, but I don't think it is going to be my last.

Hope this helps.

From: brendan4933
Topic: 5420 Message: 5420

Hi group

I would like to try and make a 80mtr vertical out of a silver rod.
Has anyone tried this, if so what was there results, and how did you
do it.
For example: how long was the vertical,what was the coil spec, and
did you leave the 50om matching coil in line. Could you work 40 and
20 mtr though a tuner.

Thanks group

Brendan 2E0BDS (Sunny England for once)

Well, Jim, if Alpha Delta ever wants someone to Beta Test a 160/80/60 and possibly 40 m DX-LB, I will be happy to do it.
I have 35 countries on 60 meters since last September and popularity worldwide is growing.

Jim

Thanks for the info.

Presently I use the 102 ft G5RV on 80 and 160. Too short for 160 but it works well enuf to get a clean sweep on VP6DX. The short lengtrh on 160 means a lot of tuner adjustements. I also use teh G5RV on 60 meters with the tuner.

My plan is to use the DXLB on 160, 80 and 60 meters. I plan to use a tuner again on teh LB and am hoping that it will perform equally well on 60 as the G5RV does. (Worled AH2L on teh g5rv on 60 m.

The G5RV is mounted as inverted V 30 ft at teh apex. Plan is same for the LB. Do you see any problems with this arrangement? I want to use the MFJ auto tuner on the LB and eliminate the manual Versa Tuner completely. The MFJ auto tuner is supposed to be able to handle a huge range of impedance up to 3200 ohms.

Subject: Re: [ham-antennas] RFI in the shack with Alpha-Delta DX-LB Plus

Hi Dan,
Yes, I know a little about this antenna as I have worked for Alpha Delta for 15 years now. I'm sorry if my response sounded like an advertisement; it wasn't meant to be.
The SEP cartridge which is located in the center insulator contains a gas tube which will drain off a static charge once it reaches a critical level. Also, it could be argued that the device provides some degree of protection from lightning induced surges although since there is a relatively long path to ground through the coax shield and since that ground may be your radio's chassis, lightning protection should be provided nearer to a heavy grounded point such as at the point where the coax enters the shack. The problem sometimes encountered with the SEP is that many hams use tuners to feed the antenna and thus get power into the antenna at relatively high SWR's at the feedpoint. If you can tolerate the feedline losses at these elevated SWR levels all is OK unless the high SWR causes the RF voltage at the feedpoint to exceed the breakdown voltage of the SEP cartridge which is 1KVDC. At transciever power levels (100W - 200W) this is not a problem even with moderate SWR but, as power and SWR increase, the gas tube can go into conduction which produces a "short" at the antenna feedpoint. This, of course, isn't good but the tube quinches as soon as the power is removed. This sometimes happens only on modulation peaks. Since the DXLB and DXLB+ cover 160M with a narrow 2:1 bandwidth (typically 20 KHz) most operators are using a tuner to get some extra bandwidth. Considering that the SEP was being driven into conduction quite often

on the DXLB and DXLB+ due to a combination of power and SWR from the use of tuners, the LB series is no longer shipped from the factory with the SEP installed. It's an easy job to remove the SEP on earlier models but there is no reason to do so at moderate power and SWR levels where the problem has not been observed.
Regarding the inductors as to whether they are loading coils or traps, the answer is simple, they are both. The inductors act as loading coils to make an electrically short section of wire resonate at the desired frequency. Also, at another range of frequencies, for instance 7 MHz to 7.3 MHz (40M trap, 80M/160M loading coil), they act as traps, actually resonating with the distributed capactance of the inductor's windings. No trap capacitor to blow !
I hope this explanation is helpful and I apologize for being "longwinded".

Jim

Sounds like you are technically savvy on this antenna. I read a post where a ham had problems with the DX-LB and when he removed the arc plug, it worked great. Any comments on this?

Also, are those loading coils or traps on this antenna? If loading coils, how do they make the antenna resonate on 40 and 80 without trap capacitors?

Why silver?? Seems like a very expensive way to build a verticle. The difference in resistivity (Silver=1.59 vs Copper=1.72) is negligible. I think you would have much better efficiency and bandwidth if you used large diameter metal tubing and not worry about the small difference in resistance of the material used.

Don and the group,

I just switched coax and as expected the DX-LB Plus is no longer deaf on 20 meters. Before I changed the coax I could switch from the beam to the dipole and I wouldn't hear anything. Now I can switch from the beam to the dipole and I am now hard press to tell the difference.

I still have some RFI in the shack. It is down a lot, but still on 75 and 40 meters. The RF choke is now only about 6" in dia. I don't know if that makes a difference or not.

I am going to try to shorting the run from the T1 smartjack to router which I hope will help in two ways, 1) It will get the router farther away from the feed line and two it will shorting the cat5 length.

Any other suggests would be welcome.

thanks and 73

If you still have RF in the shack, take a look at your grounding scheme.

Invariably, RF in the shack will also get into your transmitted signal and you will get lousy reports on SSB and even CW and in digital modes you will clobber the band with spurious emissions.

I had RF in the shack once and instead of people being polite and informing me and maybe even offering advice, they would just call me a LID on SSB or on CW. This is infuriating. Makes my blood boil. One guy, a tech rep for Icom heard my signal and actually emailed me and discussed the problem, offered suggestions and ultimately I resolved the problem.

Is it the T1 line itself that is picking up RF or is it a wireless hub? If you connect the LAN cable direct from T1 to PC and turn off power to the wireless hub, does the problem go away?

Maybe the AC/DC Wall Wart on the T1 or Wireless hub is picking up RF. Maybe some Ferrite clamp on cores on the Wall Wart cord will fix it. I saw an article in QST where a Wall Wart was radiating trash into the author's rig. But maybe the reverse can happen also.

My problem only occurs on 160 meters using a G5RV. 80 and 60 meters are OK on the same antenna. I Never use the G5RV on any other band.

BTW, 8 ga aluminum wire may not be good enough for RF grounding. The recommendations seem to be tin plated copper flat braid 1 1/2 inches wide. Remember that RF travels on the outside of a conductor and copper is a better conductor that aluminum for RF. Braid has many conductors, better for moving RF to ground.
Is the outside ground rod also connected to the ground rod where the AC mains come into the house? It should be but not always convenient.

Subject: Re: [ham-antennas] Re: DX-LB Plus with RF choke

Hi Dan and the group,

I am getting good signal reports. I have 8 ga aluminum wire running to
a ground rod outside my shack and 12 ga copper wire from my equipment to
the grounding bar that the aluminum wire is connected.

Even the computer speaks aren't picking up the RFI, just the T1 line.
Would making another rf choke with the coax closer to the shack help?

What about putting foil around the coax in the shack and grounding it help?

thanks

Darryl,

In another life I was VP of Ops for a couple phone companies. At some locations we would encounter stray RF on T1's. WE use ferrite beads on both ends of the T1 lines and the problem went away...with one exception. At one location we discovered a bad MUX. We changed it and added the beads and all was well.

It is the T1 line itself. I have 2 wireless routers, but is being feed via ethernet. On a side note, when I tune to 6 meters on my A3S it will crash the wireless router which is about 30 ft above the A3S beam.

I put shielded cat5 cable between the T1 Smart jack and the router CSU port.

I will try the ferrite beads next. It is like 95% fixed. Before when it hit the autotune on the 746 it would crash the T1, sometimes hard enough to require a router reboot to solve the problem.

Now it just seems to drop carrier and come right back up.

Thanks for all your help!

Almost sounds like another bad RF connection. Maybe a cold solder joint on a coax connector. The cold joint will have an impedance which will develop RF voltage across it.

What you want to do is get to the root of the problem, whereas using ferrites may be a bandaid rather than a cure.

Why don't you get some clamp on ferrites? Should dampen the RF coming
down the coax.

You'd be much better off with 1.5" to 3" copper strap, or flashing. Over time, the strands of the braided cable can become dirty (for want of a better term) and begin to act like many fine wires in parallel, with an attendant rise in self inductance. The copper strap will have much more capacitance because of the large surface area which makes it a better low impedance conductor. See this all the time in lightning protection.
Aluminum should work just about as well, as long as you make sure it is well bonded and stays that way.

Another consideration, is the length of the grounding run. If the lead is a quarter wave long (or any odd quarter wavelength) at any of the frequencies you use, it will act more like an open circuit for RF. The inverse of that has been used to clean up hot transmitter chassis' by connecting a quarter wave length of wire to it, the far end left open. The chassis end actually forms a low impedance and can relieve some problems. Think of it as a single radial.

Stan

Subject: Re: [ham-antennas] Re: DX-LB Plus with RF choke

BTW, 8 ga aluminum wire may not be good enough for RF grounding. The recommendations seem to be tin plated copper flat braid 1 1/2 inches wide. Remember that RF travels on the outside of a conductor and copper is a better conductor that aluminum for RF. Braid has many conductors, better for moving RF to ground.
Is the outside ground rod also connected to the ground rod where the AC mains come into the house? It should be but not always convenient.

5435. Extensive list of HT and HT related accessories FS

Yahoo group: ham-antennas (2008)

From: Ken Simpson, W8EK
Topic: 5435 Message: 5435

Extensive list of HT and HT related accessories For Sale:

I know this is a long list; I have tried to group similar items together.

Alinco DJ-191, 2 meter HT
This unit has about everything except the kitchen sink in it. It has a very large, readable LCD display that I can read without my glasses! It has about 7 watts max output, and the receiver is great. It covers from 136 to 174 MHz, so it covers all of the weather and VHF public service frequencies. Of course it has memories and all sorts of scan features. Touchtones (DTMF) and PL (subaudible) tones are included.
This unit works 100% and looks extremely nice. It includes a good battery pack, belt clip, rubber duck, and paper work for $100.

Radio Shack 19-300 Battery pack for HT-202 and HTX-404
This is a good battery pack for the Realistic HTs. It also fits some of the Icom HTs such as the IC-2 AT, IC-02 AT, IC-4 AT, etc.
This is the 7.2 volt, 600 ma hour NiCad pack.
It works fine and looks great. $25

Icom BP-3 battery packs
I found four of the BP-3 battery packs that are all dead. These packs were used on the IC-2 AT, 3 AT, 4 AT, 02 AT, 03 AT, 04 AT, and maybe some others. They can also be used on the Radio Shack HT-202 and HTX-404, and maybe others.
All of these are dead, but if you need a battery shell, to put a new "insert" in to, it would be ideal. $8 each

Kenwood SMC-24 speaker microphone
Fits Kenwood TR-2400 HTs. $18

Hustler SF-2 antenna for 2 meters
This is a 5/8 wave antenna with about 3 db gain over a quarter wave antenna. It is about 4 feet long, and is made to screw into a standard 3/8 inch 24 thread mount.
It works fine and looks fine. $15

Hustler RSS-2 stainless steel resonator spring
Recommended by Hustler to go at the top of the masts used with HF resonators, and below the resonator, to prevent breakage, in case the resonator hits a tree limb.
This one looks very close to new. $10

Larsen VHF and UHF Mobile Antennas:

Larsen NLA-150, 2 meter antenna, for Larsen NLA mount
Has about 3 db gain on 2 m; includes whip. $16
As above, but without whip. $10

Larsen NLA-450 coil and "stacked" whip for 440 MHz
Fits the Larsen NLA mount, and has about 5 db gain on the
70 cm band. Stacked whip is included. $12

Larsen NLA-Q
Fits the Larsen NLA mount, but is a quarter wave antenna.
Can be cut for 2 m, 220 MHz, or 440 MHz. $7

Larsen Q
Fits a 5/16 inch stud, such as the Larsen LM mount, and others.
It can be cut for 2 meters, 220 MHz, or 450 MHz bands. $6

Larsen NMO-Q
Precut for 450 MHz. New, still in bag. $8

Larsen OM-450 coil, mount, and whip for 440 MHz
Made to mount on a flat surface
Includes "stacked" whip for 5 db gain on 450 MHz. $18

Avanti / Antenna Specialists "On Glass" antennas:

These antennas were made by Avanti, and then later by
Antenna Specialists, to mount on a windshield, or other
glass. They do not require a ground plane, as they are
1/2 wave antennas, rated to have 3 db gain. They are
ideal for places where a ground plane is not available,
such as a boat or motor home, in addition to cars. A
special tuning box is included to match to your particular
situation.

Antenna for 2 meters
This one is in extremely nice condition, with a new packet
of the special mounting glue that is furnished by Antenna
Specialists. $28

Avanti Antenna for 440 MHz
Still in its original tube, unopened. $33

Rubber Duck and telescoping antennas for your HT.
All are for 2 meters, are in good condition, and are $10
each, unless stated otherwise.

5/16 inch threaded, like used by Motorola and others - $10 each
Regular - 5.7 inches long
Stubby - 4 inches long

Type F connector - 6.5 inches long - $10

PL-259 connector - 6.5 inches long - $10
HyGain 275, still in original packaging

PL-259 connector - Stubby - 4.6 inches long - $10
Centurion, still in original package

Special for Kenwood TH-21 HT threaded connector
Aftermarket stubby, 3.5 inches long - $10
Kenwood RA-6 regular, 6.6 inches long - $12

Telescoping quarter wave antenna
This antenna extends to a full 19 inches, but telescopes down
to about 4 inches. It has about 6 db gain over the typical rubber
duck antenna, and has a PL-259 connector. $12

Quarter wave telescoping antenna
As above, but with a right angle bend in it, and PL-259
connector. $15

Belt Clips for various HTs
$8 each
Motorola, with hardware
Kenwood TR-2400, with hardware
Yaesu FT-209, with hardware

Wrist Straps for various HTs
$4 each
Kenwood TR-2400
Kenwood TH-21/31/41
Yaesu FT-209

Santec HT Accessories For Sale:

Leather Case for Santec HT
This is a real Bianchi Leather case -- not a vinyl case.
It fits most of the Santec HTs, such as the HT-1200,
ST-142, ST-144, ST-440, etc. The real leather case
includes a built in belt clip, plus a removable leather
shoulder strap.
The case itself is in very nice shape. The leather
shoulder strap has not been used. $25

Santec ST-142/144 "Service Pack"
This is similar to a service manual, but Santec calls it a
service pack. It has schematics, circuit explanations,
voltages, etc. $18

Kantronics Cable
This cable is made to plug in to the 9 pin DB-9 connector
that is on the back of many of Kantronics TNCs and other digital
units (KAM, KPC-3, and others), and is made to interface it to
the radio.
It has a DB-9 connector on one end, and is in extremely good condition.
The connectors are labeled "1" and "2", with "1" having a red 3.5

mm plug, a white 3.5 mm plug, and a black 2.5 mm plug. The "2" is the same as "1" except it does not have the white 3.5 mm plug. It is $20

Battery charge cable for Kenwood TR-2400 HT
This is an adapter that permits one to charge the battery of the Kenwood TR-2400, 2 meter HT, outside of the HT itself. Usually, one must have the battery inside the HT, but this lets you charge a second battery outside of the HT. The original charger is used. It is in good shape, and works fine. $3

BNC to PL-259 antenna adapter
For use with any HT that has a BNC connector (such as the DJ-191 above, but many others). It will convert the BNC connector on the HT, so that you can use a normal antenna with a PL-259 connector. Like new. $5

Antenna adapter for Kenwood TH-21 / 31 / 41 HTs
This adapts the antenna connector found on these HTs to a standard BNC connector. $4

Coax connectors and adapters:
Prices are per connector. Several of each are available. These are NOS (have not been used).

BNC male
standard type - $2
crimp on type - $3

Chassis mount BNC female
square mount (uses 4 screws) - $3
screw in type - $4

BNC 90 degree - female to male - $3

BNC "T" - two female and one male - $4

Antenna adapter to fit the BNC connector on the HT and provide an SO-239 connector that will permit a PL-259 to be attached. (BNC male to UHF female) $5

UHF Male (PL-259) to BNC female (opposite of above) $5

UHF double female "Barrel connector" (two SO-239 together) $3

UHF "T" connector with two female (SO-239) and one male (PL-259) connection - $5

Original Kenwood Operating Manuals For Sale:

All are original operating manuals in very nice, close to new condition, for Kenwood radios, unless stated otherwise.

Operating manual for TH-41A/BT/E, TH-31A/BT, TH-21A/BT/E
HTs for 440 MHz, 220 MHz and 2 meters $10

Operating manual for TH-225, 2 meter HT - Good condition $12

Operating manual for TM-221/421 2 m mobile $15

Operating manual for TR-2200, 2 meter "portable"
This is very similar to the Drake TR-22. $15

Operating manual for TR-2400, 2 meter HT $12

Operating manual for TR-2500, 2 meter HT $14

Operating manual for TR-2600, 2 meter HT $12

Service manual for Kenwood TR-2600 HT - $10

Operating manual for TW-4000 dual bander $15

Heavy duty power supply
Pyramid PS-35
This supply is good for 32 Amps Constant or 35 Amps Surge.
The output voltage is adjustable over a 12 to 15 volt range
with a multi turn pot. It has crowbar over voltage protection,
short circuit & thermal protection and features a pair of nice
large edgewise meters to measure output voltage and output
current. There is an internal fan. This is a very healthy, heavy
duty supply!
This particular unit works 100% and looks very close to new.
$135

Prices do not include shipping from Florida.

Thanks.

Resistance in material? RF uses "skin effect". Not DC current passing thru the rod. In survival situations even rope soaked in saltwater made an antenna. I agree with this respondent,use a larger diameter metalic tube for a good, wider band radiator and save the silver for the family cutlery!

Why silver?? Seems like a very expensive way to build a verticle. The difference in resistivity (Silver=1.59 vs Copper=1.72) is negligible. I think you would have much better efficiency and bandwidth if you used large diameter metal tubing and not worry about the small difference in resistance of the material used.

Brendan,
It would seem that the replies so far are from Hams who weren't ever CB'ers or they would have known that a "silver rod" is a famous CB antenna that has been around for a long time & still manufactured.
Guys for your benefit, the silver rod antenna is made from aluminium tube in 1/2 & 5/8 Wave versions so around 20ft long?, with a base matching network.
Anyway at approx. 5 1/2 metres long you are in the ballpark for a 1/4 wave on 20M, but for 80M a little short bearing in mind that a 1/4 wave on 80M is 20Metres long. It is doable with a loading coil at the base or even in the centre if you split the antenna & fit a length of insulating rod to join the 2 halves & also to wind the coil on to, but how efficient would it be? Methinks not very & you will still need radials 1/4 wavelength long (20Metres) or a very good ground connection i.e. salt marsh.
You didn't mention if you want to make a base station antenna or a portable?
There are some designs built using fibre glass fishing poles with the coil wound on to the pole (Sandpiper do one), but again even a 10 metre long vertical on 80M is short, will have low radiation resistance, & narrow bandwidth. Sure, it will radiate, but not very well & you will need a very good ground or full-length radials. Now if you have any tall trees on your property then you could make a top-loaded vertical i.e. T-shape, suspended between the trees.
As for making it multi-band, that is a totally different ball-game that I won't get in to at the moment.

Skin effect doesn't negate the importance of the material's conductivity. Try making a verticle out of a 2 inch diameter carbon tube!

5439. RE: [ham-antennas] Re: 80mtr vertical out od a silver rod

Yahoo group: ham-antennas (2008)
Date: 2008-07-27 22:48:41 UTC
From: Callum M0MCX
Topic: 5420 Message: 5439

Spiderbeam in Germany do an 18 meter long "fishing pole" which is full-sized on 80m (when you allow elevated radials to tune it).

I've personally tried an 80m vertical built onto a 10 meter pole - but with full-sized radials. I wasn't too impressed.

Skin effect doesn't negate the importance of the material's conductivity. Try making a verticle out of a 2 inch diameter carbon tube!

Carbon surfaces absorb RF (see: stealth aircraft) But if that, or any surface had a thin conductive coating the skin effect would allow the RF to travel on it's surface .

From: Gerald Gaule
Topic: 5441 Message: 5441

Had to post again...sorry..

Hello this is KE7GGV-Jerry from Oregon...I have been a HAM operator for two years..I am disabled and love the hobby..Here is my plan and scenario...I currently use a 5-BTV Vertical that is connected to my ICOM-IC 718 and I also use a MFJ VERSA TUNER III and I use a LOW-PASS Filter...I am looking at a Van Gorden G5RV Shorty Dipole w/ladder line..I have very limited space and plan to use it as a inverted V... (so far)my mast I have on the north side of the home/small lot..I mean SMALL...the mast is about 25' and How do I(the right way)drop the Ladder line???...or construct it right..I do need help...all info will be fine...now from what I understand with a tuner and like a marconi can be used at 160 meters..

Thank you for your advice.....

THX DE KE7GGV..73 TO ALL and taking the time to read this...all is very much appreciated...

Any of the mobile 1/2 wave (about 40") antennas will work. I use a dual band 1/2 on 2m stacked 5/8 on 440 on my fiberglass boat and they work fine. SWR is slightly higher than when on a car but still below 2:1.

I did ask diamond the same question and their response was the same about using the 1/2 wave antennas.

Hi Sean,
I have only ever had access to my homebrew antennas but have used both folded and split dipoles.
For what it is worth, my money goes on the regular split dipole.
I live in the worst area for VHF/UHF communications and thought 'aah split dipole less manmade noise'.
No didn't work any better than a regular dipole, also didn't get any greater bandwidth on the yagis, the gain was the same (well it would be).
It was also mechanically harder to produce a folded dipole, but is easy to build a good hard wearing split dipole.
A split dipole does need some form of balun, but that's no biggy, try a few ferrite rings on the coax at the feed point.
Or you could try wrapping the coax itself around the boom 6 or 7 times again at the feed point.
For me and possibly against what everyone else says (it is after all a personnel thing) go for a regular split dipole.
good luck
regards
Gus M0IKB

Sean's questions are interesting. I have often wondered if the "closed loop" design of the folded dipole would exhibit the same resistance to "precipitation" static that I have observed when comparing a cubical quad with a plumbers delight yagi. I observed, more than once, that the corona (?) noise generated during approaching rain and snow storms was not noticeable on the quad while, at the same time, the noise masked everything on the yagi. These observations were made on 20 mx when I lived in Texas. I have not been plagued with this particular kind of noise in Virginia the way I was in Texas and so have not pursued the matter any further. If the folded dipole does behave the same way that quad loops do, it might make a very desirable alternative to the traditional split element dipole in areas where precipitation static is a problem.

HI , Why not make a doublet , as its a radom length Dipole fed with twin feeder , or u could make the doublet out of 2 twin wires so that you dont have a center joint as both sides of the doublet will look like a invert left & right L shape. You can also if you have a half-size G5RV remove the coax connector and feed it with twin feeder. either 75 or 300 or 450 ohm thats what i have done with my 1/2 size g5rv
a mate has made his own feeder 3 inches wide with homebrew ladder supports.

I'm not speaking from personal experience, but from theory here. So you may ignore it if you like. But I thought it is worth saying anyway.

As far as radio waves are concerned, a folded dipole is not supposed to work any differently than a normal dipole. It is not a loop antenna and does not behave like a loop, which can be quieter. A folded dipole is, after all, just a normal dipole with a built-in impedance transformer, making a better match to balanced feedline. It should have a little wider bandwidth, because it is fatter than an ordinary dipole.

On the other hand, static build-up is different, and Ken makes the good point that it has immunity to static, so this is one thing that should differentiate it from a normal dipole.

Andy

5453. Outbacker Perth Plus HF/2/6 meter antenna NEW

Topic: 5448 Message: 5454

Hi, Sean.
A few years ago, when I decided to get back into ham radio, I put up a 40 meter dipole fed with 72 ohm twin lead. It was rather low, about 20 feet high on the ends. We have rather low juniper trees here in Central Oregon. An old antenna tuner matched the line to my Kenwood TS-520S. It worked, but we were living with several sets of high voltage transmission lines in front of the house. Quite noisy!

I determined to reduce the noise pickup and bought a full spool of 300 ohm TV twin lead from a seller on Ebay. I constructed an 80 meter folded dipole using the twin lead. When connected to the tuner in place of the dipole, I thought the antenna was shorted somewhere close to the garage where I had my shack. It wasn't. It was just so very quiet. I tuned around on 75 meters and heard several stations on during the day. It worked well for both transmitting and receiving.

My problem was induced noise from the power distribution lines and the folded dipole took care of it. Other types of noise, QRN, will not be reduced.

The twin lead antenna did not last through the winter, however. The wind whipped the feed line until it broke. I repaired and it broke again in a few weeks. I had to give up on it.

A later antenna, a 160 meter dipole fed with 450 window line also had feed line breakage due to the wind. It was also noisy!

My current antenna, at a different location, is a 160 meter lazy quad about 35 feet up. Fed at one corner with home made 600 ohm feed line. The wind is bad here, also, but the feed line has a very small wind resistance, so doesn't suffer damage.

The loop/quad picks up lots of QRN. Desired signals are strong, so I run my Icom 706MkII with the 20db pad turned on almost all the time.

In conclusion, the folded dipole will reduce your noise, if it is picked up from a local source, but not if it is the noise we all experience on the bands.

Good luck with your project.

Paul, KD7HB

Granted, the folded dipole is a dipole and works like a dipole, in that
it has no gain over an ordinary dipole and has the radiation pattern of
an ordinary dipole but is distinguished from the ordinary dipole in that
it has a slightly broader bandwidth.

> match to balanced feedline. It should have a little wider bandwidth,
> because it is fatter than an ordinary dipole.
>

Here we will have to disagree. While the folded dipole is only a dipole
in terms of its pattern and gain, in terms of its physical construction
it is a flattened full wave loop, fed in the center of one half wave
side. It is the fact that a folded dipole is a one wavelength loop of
wire that gives rise to my question as to whether it would exhibit the
same immunity to precipitation static that I have observed on one
wavelength cubical quad loops.
> On the other hand, static build-up is different, and Ken makes the good
> point that it has immunity to static, so this is one thing that should
> differentiate it from a normal dipole.
>
> Andy
>
>

So that I'm not misunderstood, the noise "immunity" that I observed was
limited to only the popping noise that starts out slowly and accelerates
to an almost buzz saw like sound and which ends suddenly with a corona
(?) discharge. I refer to this as precipitation static. Some folks who
live where the dust blows rather fiercely on occasions have also noticed
this effect on dry, dusty, windy days. So it isn't limited to rain and
snow. Ordinary static generated by lightning seems to me to be just as
loud and prevalent on the full wave quad loop as on the yagi. Others
may differ, saying that the quad loop is quieter in other ways too, but
that's not my assertion.

73,

Ken - K4XL

Sean, I tried a folded dipole (B&W) for field day one year, it had
nice swr, but few contacts. After an hour or so we switched over to a
standard dipole and the contacts piled up. I can't say about noise as
we were miles from civilization. I can't recommend the B&W folded
dipole at all..hope this helps, 73 Alan

i have on set for 40 meters it took a bit to get the vertical wires tuned here but works well for 40 meter contesting unfortuneitely it runs east and west so works north and south . from alaska to south america anything i hear i can work ,, i just did the corner connection like a dipole shield to the vertical and center of the coax to the hortozonial wire.. use it with 100 watts and get good signal reports ,,

5464. My Horizontal Half Wave Open Loop - Performance questions

Yahoo group: ham-antennas (2008)
Date: 2008-08-02 01:56:19 UTC
From: Jonathan Helis KB5IAV
Topic: 5464 Message: 5464

For the last several months, I've been experimenting with a horizontal half wave open loop in the attic of my 1 story house. It's basically a dipole in the shape of a horizontal loop 25ft x 5ft, for a total of 60 feet of wire. It's fed with 300ohm TV Twinlead, a 4:1 balun, and it's tuned with an LDG Z-11 Pro autotuner.

I've been working alot of PSK31 not running more than 40 watts and here are the results I'm getting:

On 20 meters, I've been able to work Alabama, Floriday, Georgia, Kansas, Kentucky, Michigan, Missouri, New Mexico, New York, Ohio, Pennsylvania, Tennessee, Texas, and Wisconsin. On the DX front, I've worked Guatemala, Cuba, Costa Rica, and Puerto Rico from my Louisiana QTH.

On 40, I've worked Florida, Indiana, Kentucky, and Oklahoma.

With some of those close in QSOs on 20, I wonder if my antenna is a cloud warmer.

I've tried loading on 17, 15, 12, and 10 and haven't made any PSK31 contacts.

I was wondering how that performance compares to what others are getting right now. I'm thinking of replacing the antenna once summer is over and I can get into the attic, possibly with an OCF dipole or something like that.

Any comments are welcome.

A 1/4 wave dipole is going to be very reactive and will require a tuning network in order to work, and it will work rather poorly even then. So, I assume that you are talking about 1/2 wave dipole and a simple 1:1 current balun is all that you will need. In fact, a simple choke made of six turns of your 50 ohm coax feedline wound in a 4 inch coil should prove sufficient.

Good Morning Doug!

I have built many dipoles according to the formula and attached the coax
straight to the radiating elements with great success.

!/4 wave each side , ½ wave over all??? OK , you can use a 1:1 , or a few turns of coax. If you can support it in the center and get the ends a little lower you can get the SWR down toward 1-to-1. Dipoles are closer to 70 ohms straight , towards a slight □V□ gets it closer to 50 Ohms

The only disadvantage of using both, that I can think of, is the added weight that the dipole will be supporting.

Doug , the books say all kinds of things ,choke , balun and/or what ever but
I have made just as many contacts on a plain dipole. When I make a J-Pole
for the club members I add a choke but if I put up a dipole for some one
its just a dipole , no choke or balun. I have a 5 band dipole up now at home
and it has no choke or balun on it. When I make the field day set up for the
club with more than one radio I use chokes and stubs to help with
interference. If you are doing this at home with one radio at a time, just a
wire will work fine.

From: Callum M0MCX
Topic: 5464 Message: 5474

Jonathon, basically you are doing fine. The only thing that would change your far field plot and stop any inclination of cloud warming would be height - nothing else. Pointless to try. If you are actually getting RF out the antenna (and by the sounds of it you are) then it's working as best it can.

Regarding the higher bands, it's the same for me too - basically not good for DX right now unless you are into big hardware.

Conclusion, just carry on :)

PS - of interest, what would happen if you turned this little antenna into a full loop..?

Callum, The answer is yes and no, open and closed . It all depends on what you want to pass and null and remember the velocity factor of the cable you are going to use has to be figured in. The best references are, K1TTT, Dave Robbins , and QST November , 2004 has a good chart on this by N0AX in the ☐Hands-On Radio☐. You can get the QST article from the ARRL web site or try N0AX

5478. Re: My Horizontal Half Wave Open Loop - Performance questions

Yahoo group: ham-antennas (2008)
Date: 2008-08-03 17:33:15 UTC
From: Jonathan Helis KB5IAV
Topic: 5464 Message: 5478

Thank you for your reply. Yesterday I worked Mexico, Maryland, North Carolina, and Arkansas on 20 meter PSK31. I put this antenna up because it was the best I could do with the space I had. I didn't want to do a single wire end feed even though I've had good luck with that design in the past, I didn't want to deal with the RF in the shack issues I had to deal with.

I've considered closing the loop and seeing what it does. That will probably make it's resonant frequency lower to being close to being a full wave loop on 20 meters. I went with the half wave because I wanted to be able to get on 40. When our weather cools off, I may try to get up in the attic and close the loop and see what it does.

I've been working PSK31 and having a good time. I've wanted to do digital modes for a long time and finally got around to it. Trying to get Worked All States on PSK31 and possibly go after some of the digital awards offered by BARTG.

Thanks for the input.

5480. rf exposure limits

Yahoo group: ham-antennas (2008)
Date: 2008-08-04 02:54:29 UTC
From: ve3diz
Topic: 5480 Message: 5480

Hello all. I'm wondering about rf exposure to children, mainly new born. I became a father to our beautiful little girl Thursday morning. The antenna I am using is said to have a 3 point something db gain but I wasn't sure if it was dbd or dbi so I assumed the highest. I also assumed that all of 50 watts transmitted was getting to the antenna to give me an absolute worst case exposure.
So according to an online calculator using a 6dbi omni antenna with 50 watts at the antenna at 146MHZ the safe distance for a person is 9.28 feet. Would that also include infants or should I keep the power down? I mainly use only 5 watts to hit the local repeaters but I do turn it up when using SSB and chatting on distant repeaters. I would like to get the antenna further away from me but unfortunately I'm stuck on the 3rd floor of a 12 story building with no hope of getting an antenna setup anywhere but on my porch. All tips or suggestions appreciated. 73!

Well, I applaud you for being protective of your child. I suppose you could have your baby at the opposite end of the home when transmitting. Or use a VHF beam antenna pointed away from the home(hopefully at the repeater). I assume metal screening and walls absorb RF to a degree.

What kind of door do you have going out to your porch on the 3rd floor?

If it is a screen door, put copper screen on it. That should effectively shield the interior of the apartment. Just don't thake the baby out on the porch when you are using the radio.

Hove you considered getting rid of the microwave oven in the kitchen too?

Hi
To everybody in going to build a homebrew antenna for 17m maybe 3 or four element yagi any suggestion does anybody have the dimensions for a three or four element using maybe 18` foot boom id prefer to use z match on the driven element 73`s Kp4lcl

5484. Ladder-line length for a 40m folded dipole

Yahoo group: ham-antennas (2008)
Date: 2008-08-04 23:50:49 UTC
From: jamesgeidl
Topic: 5484 Message: 5484

I have a 40m folded dipole. The more I read the more confused I get. I am feeding this antenna with 300 ohm twin-lead/ladderline. This feed line is completely insulated with openings periodically through the length but isn't even structured openings like you will find in open ladder-line. The line is about 1/2" wide +/-. Do I need to leave this feedline a certain length? I have read that it a) doesn't matter, b) must be at least full wave in length (66' +/-), c) must be at least half wave in length (33' +/-).

Suggestions. opinions, ideas?

Thanks,

Jim, K6JMG

Jim,
I can't give you the right answer but appx 10 years ago I made a swap and was given a 17 meter CW RIG with the MFJ folded dipole.
I do remember the feed line had a coax connector in the end.
My friend told me to put and length coax on the end and bring it into the shack but I think that was to keep the unshielded twin lead out where it belonged.
My shack was right next to the window so I used the twin lead right to the rig.

The half-wave folded dipole can be made resonant with an impedance of approximately 300 ohms which matches a common transmission line impedance (twin-lead). Thus, the half-wave folded dipole can be connected directly to a twin-lead line without any matching network necessary. In general, the folded dipole has a larger bandwidth than a dipole of the same size.
From what I used in the past it's no more efficient then a coax fed dipole and has no gain over a coax fed dipole.

Jim, if you're operating this antenna on its design band the length of the feeder is unimportant.
However if you plan to use this antenna on other bands with a tuner then feeder length can become an issue.
The ARRL's Amateur Handbook and the Antenna Handbook have some pages devoted to just this question.

5489. 30 Yagi

Yahoo group: ham-antennas (2008)
Date: 2008-08-05 01:48:56 UTC
From: Dave
Topic: 5489 Message: 5489

I need the help of the group. I have built a 30 meter, 3 element yagi based upon the design found in the ARRL Antenna Handbook. Actually it's a combination of 2 40 meter, 2 element antennas. Anyway, everything is together and I am now in the process of fine tuning the thing to 10.1 mhz. Initial measurements indicate a resonance frequency of 9.6 mhz with an swr of 1.1: 1.0. At 10.1 mhz the swr is 1.8 : 1. So, apparently, I have some tuning to do on the driven element. But, and here's where I need the help of the experience of reflector, the antenna, as it is being measured now, is only 5' off the ground and the element tips are only 12" - 18" off the ground (there's approximately 36" of droop - boom to tip - in each element). This has got to have some effect on the resonant frequency as I'm measuring it. Anyone have some advice on making sure this thing is on frequency before I put it atop the tower? I sure don't want to be put it up and take down multiple times for the sake of tuning. Once up, it's up, tuned or not.

Thanks in advance.

Dave,

Can't comment our your antenna but am glad to hear from someone else that it
not excited about running an antenna up and down 15 times to tune it. I
hear guys talk like that is the simplest thing in the world...not when you
are feeble.

Frankly, five feet is not a sufficient height for getting any meaningful SWR curve information. In fact, being that close to the ground would certainly make the antenna tune lower in frequency, just like yours is. I doubt that you would get a reasonably accurate curve unless you were 12-15 feet up. A 30 mx 3 element yagi is big and unwieldy, however, if you could manage to hang it on the tower at 15 feet, I think that you would find that the SWR curve will have moved up to where you would like it to be and if not, you could lower it down to ground level and make the necessary corrections.
Good luck with your tuning, OM.
73,
Ken - K4XL

5492. Explain this one - 10m Single Wire Antenna

Yahoo group: ham-antennas (2008)
Date: 2008-08-05 18:12:43 UTC
From: SB
Topic: 5492 Message: 5492

Ok - so I took the calculation for a half wave at 10m. Used zip cord/ 22 gauge speaker wire (nothing special). Never unzipped the wire. Just left the 2 conductors stuck together. Tested it and YES it did not work. So I unzipped half of the counterpoise/ wire connected to the braided part of the 50ohm coax..and cut it off. And then tested it YES it did not work (meaning the swr was not even close to a match). So I then took the driven part of the wire and pulled back and used tape to keep it from unraveling in 3 sections.. the top, the middle and then at the end I twisted it around the 2 conductors until I got a match(4 to fove turns..very sloppy turns).. I got a 1:1 match. I tested it in the basement and it was ripping through the phone making the lights glow! Ok.. now I took it outside and did the test in a vertical position and WOW I am hearing stations on 10m. Ok ☐ So its only 1 foot off the ground being supported by a wooden post I used for a bird house. Clear of all metal and got a 1:3 swr ☐ pretty happy..The 10m band has been pretty weak.. tried calling but no luck. No local stations to test it with; but its receiving and is a match. Why? Ugly as sin. Would need a plumbers tubing to support it next time around and I will test it again... but very odd why it works or even matches less a tuner.

Ok to follow with this odd ball antenna.. I tried it this afternoon
at 14:30 EST and 10m was open here... I worked 2 stations one in Ohio
and another in Arkansas. Compared against my commercial antenna and
it was 1-2 units less + it picked up 3 units of static..as where my
commercial antenna did not.. The commercial antenna was on mag mount
on top of my van. And my wonder wire was place 1.5 feet above the

ground and suspended by a tree branch. Well for an emergency type antenna ☐ it works. Next will be to place it in a plumbers pipe and actually mount it up much higher. Mind you,.. if the static continues.. forget it ☐ way to noisy. But it does emit a signal..an on 10m I can dig that.

I'm having a little trouble understanding your descriptions.

"YES it did not work" ... do you mean the SWR was bad, or that you weren't heard and/or didn't hear others?

Half-wave end-fed? Half wave dipole? Center-fed? Coax fed, no balun, right?

What exactly did you change to get from a huge SWR to a 1:1 match? All I can tell is you apparently removed insulation (somewhere) and applied tape, which should not have changed much at all, if the conductors are still in the same place. If the SWR reduced by that much, then I'm guessing something else was going on, like a loose connection.

Andy

I had taken the assumption that it would not work. Meaning a high swr and could not tune it with a tuner.. well from the little attempt I did, it would not tune. No balun and swr 3+. The wire is end feed. Keeping the 2 wire intact.. until half way I cut off the wire connecting to the braided part of the coax and then took the driven piece of wire that was now single and pulled it back and taped it to avoid it from coming apart and then taped it also in the middle and finally..at the end twisted it around the 2 conductor piece of wire and adjusted until I got a match.. did that make sense? I have photos of this ugly wire antenna.

5496. EVX6000 Anybody had a go with this antenna ?

Hello Ham Antenna Group,

More antenna doodling.....this
time a remotely tuned loop antenna
using just a capacitor, a motor(stepping?)
and a potentiometer. Read the voltage
on the pot for a crude analog memory
or get fancy with a shaft encoder, SWR
bridge and microprocessor for a full
blown autotune antenna. See
http://ph.groups.yahoo.com/group/ham-antennas/photos/view/f4ef?b=13

Cheers.

5499. Larson NMO 2/70 Swr question

Yahoo group: ham-antennas (2008)
Date: 2008-08-13 01:55:58 UTC
From: Joey
Topic: 5499 Message: 5499

I have a question. I have a Larson NMO 2/70 antenna mounted in the middle of my roof on a 92 Chevrolet pickup. Tonight I borrowed my friends MFJ antenna analyzer to check the antenna, well the meter reads the following. 144-145mhz 1.6swr and 145-148 1.5swr and a flat 1.5swr on uhf. I have tried to get the swr down a tad but I have been unable to. I thought maybe the mount was not getting a good ground but it is and and I have checked it twice. I know it is grounded because I can connect my multimeter between the plug shell and chassis and get continuity. I don't know what else to do? Has any one else had this problem with this antenna? I was thinking of cutting maybe a little off the end in hopes the swr would come down any one done this? Also I assume that a swr of 1.5 wont hurt the rig? I know 2 or more is bad. Any Ideas?

Thanks,
Joey

Hello Joey - Assuming that your analyzer is giving you a
correct reading , I am thinking it all probable your antenna
is to short by a small amount - If you lengthen it, will it not
drop further still on your higher vhf freqs? All the while
keeping an eye on your UHF so as not let it take off to far.
A reading of a 2. should give you a reflected power of
around 11% - a 1.5 should be close to 4% - If I can assist in
any way feel free to call - 73
Dave / N?ATH

Your 440 SWR is lower because for a shorter antenna it is looking at a lager ground plane.
The 1/5 is 100% acceptable but check your SWR at the bottom and the the top of the 2 meter band and see what kind of readings you get then post them here.

At 1.5:1 I wouldn't even worry about it. Your radio will be fine and
with the amount of coax you are running the loss won't be an issue.
Don't worry just be happy.

Bob,

When using the meter I get 1:6:1 at 144mhz and 1:5:1 at 148mhz. I take it that the antenna is a little short? If so how can I lengthen it? I have not done any cutting on it as it is stock.

Thanks,

Joey

Thanks for replying,

Thanks for the reply, I have a question regarding swr. I take it that 1:5:1 won't hurt a radio or damage it correct? Now on the other hand anything over 1:5:1 is not good and can damage the radio correct? What I am trying to say is what is the maximum swr reading that won't damage the components in the radio?

Thanks,

Joey

It depends on the radio. My Yaesu FT90 and FT8900 have the fold back feature set at 3:1. My 857 is somewhere around 2:1. I wouldn't be concerned until you get over 2:1 but would be real concerned at 3:1. Best thing to do is call the radio manufacture and ask if they have fold back and if so what SWR it kicks in at. Anything under the fold back point the manufacture considers safe for that radio. If they don't have fold back they would probably tell you where you need to be concerned but I would be surprised if they worried about anything under 2:1.

Larson optimizes for FM section of the band. Your flat reading on
145-148 of 1.5:1 agrees with that. They are a little short because of
favoring the upper end of the band. You can try moving the whip out to
the point the antenna is just barely held by the set screw but I doubt
it will buy you much.

Thanks for replying,

That makes me feel better. I have a 857D and a FT7800 so I think I might be ok after all.

Thanks for the comments.

Joey

To: ham-antennas@yahoogroups.com
Subject: Re: [ham-antennas] Larson NMO 2/70 Swr question

It depends on the radio. My Yaesu FT90 and FT8900 have the fold back feature set at 3:1. My 857 is somewhere around 2:1. I wouldn't be concerned until you get over 2:1 but would be real concerned at 3:1. Best thing to do is call the radio manufacture and ask if they have fold back and if so what SWR it kicks in at. Anything under the fold back point the manufacture considers safe for that radio. If they don't have fold back they would probably tell you where you need to be concerned but I would be surprised if they worried about anything under 2:1.

From: J. Harrell
Topic: 5499 Message: 5509

Your exactly right, I tried to move the antenna out to the point of barely being held in and it didn't do a thing. I think I am going to just let the thing ride like it is. I don't think it will hurt me FT7800 anyway.

Thanks,

Joey

Subject: Re: [ham-antennas] Larson NMO 2/70 Swr question

Larson optimizes for FM section of the band. Your flat reading on 145-148 of 1.5:1 agrees with that. They are a little short because of favoring the upper end of the band. You can try moving the whip out to the point the antenna is just barely held by the set screw but I doubt it will buy you much.

Joey,
The SWR is fine.
The biggest harm to any radio is HEAT so you don't want to use more power then needed.
The dual band is optimized for 440
You can also see how much RF is on the coax buy using a florescent tube and have someone hold down the MIC button.
On my antennas I use top quality cell phone coax

5512. windom antenna

Yahoo group: ham-antennas (2008)
Date: 2008-08-13 16:03:41 UTC
From: steven17071969
Topic: 5512 Message: 5512

I am quite new to this so if anyone can help it would be very appreciated. I am thinking of making a windom antenna for my garden. Would it be ok to have the antenna sloping down the garden? Say 35 foot at one end and 20 foot at the other?

5513. Mobile Mismatch - any ideas?

Yahoo group: ham-antennas (2008)
Date: 2008-08-13 16:21:04 UTC
From: SB
Topic: 5513 Message: 5513

I tried my FT100D in the van for the 1st time last night. When I connected the antenna through the SWR meter (10m antenna connected) it was a good match less than 1.5. Then I connected my old MFJ-949E antenna tuner to tune anything higher when I climbed up the band. Well I tested it with the built in dummy load and it was fine. Then I tried bypass (at the same location of where I was 1.5 without the tuner) and the swr climb into the red pass 3(odd - really odd). I tried tuning it in the tuned position and I couldn't(would not budge). I removed it and all was fine without the tuner on the line. I then grounded the tuner andstill the same reaction.

I then tried the tuner inside the house on a wire antenna laying on the floor and it tuned it (not with the same radio - but with the same patch cords) it worked 100%.. tuned the wire no problem.

Any ideas why or what I'm doing wrong. I did not ground the radio nor the antenna, as it's a magnet mount (I could try this also.. but I have my doubts).

Did you use the same antenna side connector on the MFJ for both tests?

I cannot see the insulators you mention, at least not clearly enough to identify them.
It is a simple dipole, from what I can see, not sure why the coil though.
Unluckily, I lost the old handbooks I had, and newer ones hve fewer details
The only item I have left from that time, or older, is a soldering iron that my dad said was mine. And not sure I even want to plug it in, as the cord is hard, as I recall, and the tip is flakey/corroded. I recall tinning one with a Sal Ammoniac block many years ago. Hard to imagine soldering connections with the beast now. Had a number of irons through the years.
My first Novice antenna was an end fed wire, circa 1973, give or take, with a home brew tuner.
Rochester NY to Washington state on 15 at night.
For the record, I am, and was, the only ham in my immediate family, AFAIK...

What time zone? Kind of odd hours for UTC time.

Steven you may want to try for your space this.,if you are set for Windom.
should work 40-10
total length 66ft
short end 25 ft
long end 41 ft
basic for windon is 1/3 2/3 ocf
here are a couple of links....may have to scale for you area of garden space
http://www.radioworks.com/ccw40.html
http://www.g4nsj.co.uk/windom.shtml
good luck

Yes I used the same in connector and I also tried the other connector...same results

Yesterday, I tried it again. This time I removed the SWR meter and it worked with the tuner fine. I measured my SWR using the light bar SWR meter in the rig. BUT - The antenna starts acting up after longer periods of transmissions. The swr starts to climb and then BOOM, it flairs into the red. I think I found the issue. Mind you I was stationary and I thought maybe the antenna had a broken joint or something... so I grabbed the whip and let it shoot around, keyed the rig, no changed.. same results ☐ meaning back to normal and then it starts to climb. The antenna has issues 100% - time for a new mobile antenna. But all fails with both the tuner and swr meter on the line the antenna has a social problem of some type.

5524. Hamstick band

Yahoo group: ham-antennas (2008)
Date: 2008-08-14 12:38:54 UTC
From: James - KB7TBT
Topic: 5524 Message: 5524

I have a hamstick here that I don't have a clue what freq. it is on. I have tried to contact Lakeview and they are taking guesses at what it is. I would have thought they would know what they have and make but apparently this is not true.

I am guessing it is a 20M, Lakeview says "maybe a 17M".

On the bottom there are 3 wraps of wire in a 12 inch area.

The main section or coil has about 30 smaller wraps.

At the top there is 3 wraps within a 6 inch section.

Then you have the standard whip.

Anyone have an idea?

James

The easiest way is to put an SWR meter between the rig and antenna and then try to tune on each band. Look for the lowest SWR per band.

If you have access to an MFJ Antenna analyzer, it will also tell you the resonant frequency.

Best Regards

Been reading this thread and find it difficult to follow just what your doing.
Question 1
When you tune the wire on the floor are you using the jumpers on the back of the tuner?Question 2.
Wht are you using an external SWR bridge when the tuner has one built in.
You then try the wire with a different radio.
It seems more like a thermal problem to me but leave the rig in the car/van and try a mag mount antenna for a different band.
Changing radio then trying a long wire on the floor just gets you lost.
Try low power and a different inductor setting on the tuner
Adjust the antenna for the lowest SWR before you rry to tune it.
Many hams just slap on any antenna then try to let the tuner do the job.
Try a different tuner.
Place a dummy load and a SWR meter at the end if the coax then run medium power for a while.
If things stay stable then you can rule out any thermal problem in the tuner or rig.
Make a small dipole 1/2W long.
Doesn't have to be high.
It;s only 16+ feet long.
Load into that.
If every thing looks good then the coil on the mag mount may be heating up
Just my 2 cents wiorth.

Yes that would be the easy way out, but I have never been one to take the easy road...hi hi.

I really don't have anything to mount this to at the moment, I can come up with something and pull a rabbit out but I thought that if maybe there are some folks on the list that had a few of these I could get a quicker answer. I have a ball and spring mount, maybe ill just vice grip it to the fence and see what it does..

As far as an analyzer, I wish I hade one.. Still on the xmas list..

I wonder, SB, if you might have some sort of instability in the radio's final amp.
Not that the radio is defective mind you, but that the combination of cable lengths; the environment, the stuff in the line and THAT particular radio are adding up to a problem.
If you can get hold of a broad band, and I mean into the VHF regions, field strength meter and set it up to monitor the radiated field, I wonder if you'll see an increase in field strength when the system goes postal.
A nice wideband spectrum analyzer would be 'the' perfect tool, but not too many folks have them just laying around in their shop.
Even one of those hand held frequency counters might be useful, if the parasitic (if one is really there) is strong enough to override the frequency the radio is supposed to be putting out, one with a great enough frequency range.
While manufacturers do test their stuff for "All" circumstances, we do have an annoying habit of coming up with the odd bit... ;-)

Good hunting,

Stan

When I had that kind of intermittent problem it turned out to be the coax I had going to the antenna mount. In one case it was a cold solder joint in the PL259 and in the other it was a problem with the lug at the antenna mount. I would start by replacing the connectors on the coax to the antenna.

I used a windom for years which was made by Friztel in Germany. Worked fine on 80/40/20/10 meters. I did not have a tuner in those days, I just loaded up the PA directly in to the coax. Used it mainly on 80/40 since I had a 3-el beam. Enjoy it, it is fine antenna.. Yes, one end drooped to about 20 ft, the other was high up in a tree.

Date: 2008-08-14 15:14:34 UTC
From: Kevin
Topic: 5532 Message: 5532

I am looking for suggestions for new antennas for my station.
My Station:ground mounted Hustler 6BTV, Cushcraft D4 rotatble dipole
at 40 ft and three 20meter slopers on the 40 ft tower with remote
switching. FT-890AT 100watts.
The main issue is "EARS" normally if I can hear I can work them.
The D4 is the best antenna I have up right now.
My location is a suburb w/restrictions but they allowed my tower. They
may not allow a beam on my tower??
I have 153 countries worked with 121 confirmed.
I mainly work DX.
I got my ticket and went onto the air 03/2007.
So!!! I need an antenna with the best RX/TX that will out-do my D4.
Not really interested in power amps.
Any ideas?????

Thanks
K9KDS

From: Doug
Topic: 5536 Message: 5536

Hello group,
I just rescued two folded dipoles from my place of work. They were probably constructed for the commercial band, about 400 Mhz+. Can these antennae be modified for 2m use? Any ideas out there?

Cheers!
Doug...

Going from 400+ to 144 MHz would be quite a challenge. Doing it right probably requires starting over. The dipoles need to be about three times as big as they are now.

Save them for something else. Such as 70cm.

Andy

There's the formula for figuring out how long dipole should be.

Find the length of a dipole

Freq. in MHz

The total length of your dipole is:
It will be on a side.

144 MHZ total length is 3 ft 3-1/32 in

each side 1 ft 7-1/2 in

if We do the 440 MHZ

Total Length 1ft. 0 - 25/32in.

each side 0ft. 6 - 13/32in.

http://bfn.org/~bn589/antenna.html

Check it out using calculator

From: ash_lee52
Topic: 5532 Message: 5540

A very efficient (directional and low angle) DX antenna is a half square. These can be mounted very close to the ground. Essentially the antenna is 1/2 WL across the top with 1/4 WL wires hanging down at each end and fed on one corner. So you build it like a dipole with 1/4 WL on one side and 3/4 on the other. The top can be just over 1/4 WL up (for 20 meters thats 17 feet. Support it by the coax at one end and with a line to the opposite corner of the other end. It's very light so you only need minimal support line. It is very inconspiculous and gives you the performance of a beam.

One question for the group... using EZNEC I modeled this antenna upside down, putting the horizontal element just inches off the ground. The modelling shows this actualloy improves performance... does this make sense. Essentially I believe the model says it becomes two 1/4 length verticals fed in phase... with little/no horizontal propagation.

I've only read about Half-squares, but what I've read looks good.

The ARRL antenna book (I think) says you can mount it somewhat lower if you need to, by bending the vertical ends inward, or even by angling the vertical elements as long as you keep them symmetrical. Most of the radiation comes from the top part of the verticals (where top is near the horizontal 1/2 wavelength run), so the bottom ends are much less critical.

> One question for the group... using EZNEC I modeled this antenna upside
> down, putting the horizontal element just inches off the ground. The
> modelling shows this actualloy improves performance... does this make
> sense.

I think it may. The horizontal wire is the counterpoise, so it normally doesn't need (or use) a good ground or radial system. Inverting it makes it a low elevated counterpoise/radial, and may get some added benefit by working off the ground too, if the ground in your area is good.

On the other hand, inverting it also moves the high current point close to the ground (earth), which means there could be higher ground losses because of mirror currents in the soil. Ground losses and their effect on efficiency are sometimes not modeled very accurately in antenna modeling programs.

5542. Create RC5-3 Rotor Control

Yahoo group: ham-antennas (2008)
Date: 2008-08-18 22:06:14 UTC
From: William Trippett
Topic: 5542 Message: 5542

Hi everyone. I am new to this forum so I hope someone here can give me some help.

I have a Create RC5-3 Roptor and Rotor controller. A while ago the indicator on the controller quit working. The rotator continues to set the direction as indicated on the Preset Knob but the indicator just sits in one place.

The check everything out I brought the rotator down and went through is carefully. The potentiometer in the rotator is working correctly (and if it didn't I am assuming that the preset would not drive the rotator). The connections are ok and everything seems to be feeding into the controller properly but it still does not indicate the direction on the dial.

I do not have a schematic of the controller so it is hard to guess how the indicator works. It operates off of what appears to be a small worm drive which has the direction indicating needle on it and also has a small spur gear that drives a potentiometer on in the controller. The worm gear dirve is connected to a circuit board with ICs and transistors.

Is anyone familiar with this unit? Any suggstions?

Thanks.

Years ago I read that you can use Mazola or any other "cooking" oil
with a slight reduction in power-handling capability. If I had one
today, I'd sure do that instead of the original transformer oil.

Is the old-style Larsen 2-70NMO antenna, with the CLOSED coils still available? Recently, I called three different stores, and all the had were the new, black antennas, with the air-wound coils.

Thanks,
Earl

I would think that cooking oil, once it goes rancid would be less than desirable in the shack.

Doesn't show in their online catalog. They only list the NMO2/70B. The still list it for the commercial band as NMO150/450C but I don't' know what it would take to bring it into the ham bands.

What's wrong with the open coil?

Hello all;

You might want to consider the Antenex, now Laird version.
My 2007 price guide gives the C144/440C as listing for 52.00.
Add ten more if you want the version with the shock spring, the C144/440CS.
They've worked well for me.

While I deal through a distributor (I do LMR installations & service),
I believe that you can buy direct from their website; www.antenex.com
or try this direct link, http://www.antenex.com/index051206.htm

Topic: 5563 Message: 5563

Hi,

I'm trying to sort out a better antenna system without spending too much $$. I had a thought about using the twisted pairs from Cat-5 network cable as a transmission line. This cable is designed for 100s of MHz with an impedance of about 100R. But will it work at carrying about 100W of RF (HF)? Has anyone tried this?

Of course the other way is to just build a ladder line using the wire - a cheap way to get wire since you get 8 metres of it for every metre of cable purchased. But is #24 wire okay for a transmission line?

So what doo you think? Has anyone tried such things?

Try this website. From what I remember capacitance involves frequency and inductance, not resistance.

There's a Ham in our Club club that uses 30 G Magnetic wire with a homebrew ladder line. He gets great Q's with it.

5566. Half Square Antenna versus a simple multiband delta loop

Yahoo group: ham-antennas (2008)
Date: 2008-08-21 03:19:57 UTC
From: soona4sail
Topic: 5566 Message: 5566

With some usefull suggestions from other group members, I just tried a 20 mtr half square antenna, fed at one corner, using 52 ohm coax. Fed center to one vertical, and the braid to the horizontal section, and other vertical. I also put up a simple 20 mtr delta loop, fed with 450 ohm ladder line, to a balun, then to a tuner. (gives me multi band up to 10 mtrs) In my basic tests, the half square did some good dx, and was also quite respectable in North America from this Pacific northwest QTH. The delta loop, was/is doing an excellent job on DX into Europe, and the South Pacific, but is proving to be a poor antenna for short hops in North America. I,m not sure why, but when the loop is fed with coax, the short hop communication improves, but the DX drops off. I assume the coax feed is inducing a higher angle of radiation. Both antennas are orientated in the same direction (hung from the same rope, between two fir trees)
Thanks, and comments are appreciated. VE7MTW
By the way, both antennas perform quite well, and are incredibly cheap to construct if you don,t include the feedline.

5567. 80/40 Meter Super Loop

Yahoo group: ham-antennas (2008)
Date: 2008-08-21 03:45:14 UTC
From: William Trippett
Topic: 5567 Message: 5567

I just built a Super Loop as follows. The horizontal section is 98 feet long with an insulator at the middle. Connected to the insulator is a stub of 450 ohm window line shorted at the far end. The window line was cut to 7.025 MHz using my MFJ Antenna analyzer. The sides of the loop were cut to 64 feet and tested before installing the 4:1 balun. From there to the shack is RG8.

At the shack w/o the tuner on 80 meters (3.535 MHz) the SWR is 2.0:1. On 40 meters (7.025) the SWR is 1.4:1.

It will be interesting to hear how this antenna works. I am feeding it through an MFJ high power differential tuner and external QSK switches running my AL-800 and 4-1000A amps. I'd like to hear form anyone else who has used this type of antenna.

Here's a semi-uneducated guess: don't.

I'm pretty sure there are formulas for figuring out what wire gauge to use, given wattage. I'm thinking CAT5 would not be suitable for much power at all (regardless of whether or not twisted pair would work).

As for twisted pair, since all xmission line I've seen is flat and various degrees of separated, I would reason that this is not a good idea either.

This is only my reasoning, as if I were asking myself the question. My answer is worth what you're paying for it though :)

The Alpha Delta DX-LB Plus will operate on 160 thru 10 meters as a trap dipole. They recommend 40 ft height minimum.
I use the DX-LB standard as an inverted V at 30 ft apex.
Previously I used the G5RV as inverted V on 80 and 60 meters at 30 ft apex. Got DXCC on 80, 35 countries on 60 m and with careful tuning (not recommended) got 26 countries on 160 meters. It is too short for 160 and my MFJ Versa Tuner gets hot on 160. That is why I bought the DX-LB.

5574. 80 meter loop antenna

Yahoo group: ham-antennas (2008)
Date: 2008-08-21 15:52:36 UTC
From: Dave
Topic: 5574 Message: 5574

Bill:

I use a similar loop antenna on 160, and 80 meters. My horizontal antenna is approximately 100' on bottom and top and the sides are approximately 60' in length. The bottom of the antenna is approximately 10' off the ground. I feed mine directly with 450 ohm twin lead and then to a high power versa tuner. I have puished .12 kw into it with no consequences at all, and have worked 70 countries on 80/ 75 with it. Not much experience on 160 though since it requires lots of retunbing every time I move 3 - 5 kcs or so.

Hope this is helpful

Well you could use it at 100 watts if you tied all the conductors together and soldered them at both ends and made it into homemade ladder line but I am guessing that the life would be rather short as it would wear through or the insulation would break down over a relatively short time. I use 300 ohm twin lead the good stuff and I haven't had any real trouble with it and losses are low.

5576. Antenna wire AWG / mm size?

Yahoo group: ham-antennas (2008)
Date: 2008-08-21 16:17:53 UTC
From: vaclav_sal
Topic: 5563 Message: 5576

Recent inquiry here prompts me to ask this -
what is / was a minimal antenna wire size actually used on HF by a ham
and at what power ?
I am guessing that the limiting factor is mechanical and not so much
power related.

Solid #24 AWG copper wire is rated approximately .5 A DC. I am
assuming that means continuous duty.

I have been using various antenna configurations using stranded #24 AWG
insulated wire.
I run max 100 Watts, SSB and CW.

Hi Alan and Dave and thanks for the nice replies.

I made a couple of nice contacts on 40 meters without the tuner last night (including a Hungarian station), both barefoot at 60 watts and with the AL-800 at 500 watts. I am impressed so far.

When I built it I used the remnants of my modified G5RV which had an overall length of 98 feet and calculated the length of the lower parts of the triangle after I cut the stub for the low end of 40 meters. Before I installed the 4:1 balun I measured the impedance at the feed point and noticed that it was 195 ohms on 40 meters (I did not note the complex impedance). This is pretty incredible to me and accounts for the ability to load the antenna without the tuner on 40. (The needle barely moved at my Pro III on the low end of 40).

This is surely more by accident than by design but one can be grateful for small favors.

I have not tried it on other bands yet. I do not need it on 20 (5 element monobander) or 15 and 10 (4 element tribander) so the question will be how it operates on the WARC bands. I will post a note when I have more info. Sure do wish I had a NEC to model it with hi hi.

From: Bill Lovell
Topic: 5566 Message: 5578

Interesting stuff. I've used both antennas (though my delta loop was of the 2-element variety), and had great results.

Only question, before venturing any opinions, is : How high did you hang them?

I've found that the current-fed halfsquare works best when the vertical ends are reasonable close to ground. When you raise the antenna above a certain point, the radiation angle changes.

With some usefull suggestions from other group members, I just tried a 20 mtr half square antenna, fed at one corner, using 52 ohm coax. Fed center to one vertical, and the braid to the horizontal section, and other vertical. I also put up a simple 20 mtr delta loop, fed with 450 ohm ladder line, to a balun, then to a tuner. (gives me multi band up to 10 mtrs) In my basic tests, the half square did some good dx, and was also quite respectable in North America from this Pacific northwest QTH. The delta loop, was/is doing an excellent job on DX into Europe, and the South Pacific, but is proving to be a poor antenna for short hops in North America. I,m not sure why, but when the loop is fed with coax, the short hop communication improves, but the DX drops off. I assume the coax feed is inducing a higher angle of radiation. Both antennas are orientated in the same direction (hung from the same rope, between two fir trees)
Thanks, and comments are appreciated. VE7MTW
By the way, both antennas perform quite well, and are incredibly cheap to construct if you don,t include the feedline.

From: Stan Labinsky Jr.
Topic: 5563 Message: 5581

Jeff, in a pinch, you could get by with it, most anything will radiate if set up properly and twisted pair is actually a pretty good feed line leakage wise.

Years back there were suggestions of using lamp cord as feed line and separating it to form a dipole, Zip cord is also about 100 ohms (IIRC).
However, the tech writing about it (an ARRL guy) came to the conclusion that the looses would be too great since the insulation was very lossy at RF.

If the antenna you were going to feed with the cat5 cable was presenting a non reactive 100 ohm load to it the losses would be just the simple I2R copper loss compounded by any insulation losses, which would probably not be too bad since the stuff is intended to run data at pretty good rates... another form of RF. ;-) But thin wire is lossy... any ohms in series with the load no matter how few are a loss... talk power going up in heat.

The other thing, once you move away from the antenna's matched (non reactive) frequency, you start seeing voltage and current nodes (hot spots), courtesy of the standing waves on the line. Those higher voltages and currents will increase your losses and, if they become too great, unless you are running QRP, will eventually exceed the insulation's voltage breakdown and the current nodes could heat portions of the cable to the insulation's melting point. Those would be the best reason, I would think, to go with real radio transmission line.

Another consideration, if you hooked all the solid leads together at each end and all the striped leads together you'd wind up with... 100 ohms divided by 4... or 25 ohm line.

Just the thoughts of another "Lefty".

73, Stan

> If I have a piece of wire that is 75 Ohm at 27 mhz How do I figare rhe
> capitance. I don't think it matters but the wire is 9.5 feet.

Two points:

(1) The capacitance also depends on the propagation velocity of the cable, which in turn depends on the dielectric material used, especially whether it is solid or foam.

(2) The effective capacitance will also vary with frequency, increasing towards infinite capacitance as the cable approaches its lowest resonance. The formulas probably give you the DC (very low frequency) capacitance.

On the other hand, a cable's characteristic impedance is pretty much independent of frequency.

If you know someone with (say) an MFJ-259/269, you can measure the effective capacitance of your cable, at the frequency of your choice.

Sounds like the sides are 60 ft in length, being 10 ft off ground would be 70 feet? (60+10). That's my take.

Bill,

I am confused and want to be sure I understand. You say the bottom is 10' off the ground and the sides are 60' long, does that mean the top is 160' off the ground?

From: Andy
Topic: 5574 Message: 5585

> You're absolutely correct. I wonder if that is the situation?

That was how I read it. The "bottom and top" sound like runs that are parallel to the ground and are 100 feet long, and the sides are 60 feet, and since the sides are not the bottom and top, they must be the legs going up between the bottom and the top.

Now on second reading, I note he also wrote it is a "horizontal antenna," which implies a horizontal loop, all of which is 10 feet off the ground. So maybe we're all wrong here.

5586. New Vertical Radial Field

Yahoo group: ham-antennas (2008)
Date: 2008-08-23 01:59:08 UTC
From: jsternmd
Topic: 5586 Message: 5586

Hi Group,

I am installing a 43' ground-mounted Vertical (10-160m, no coils/trpas) from DX Engineering. They recommend at least 32 radials each about 70 feet long. My lawned property is an odd shaped rectangle. If you imagine a circle divided into compass directions, N-E-S-W... I have placed 16 evenly spaced 70' radials in the due North to due East direction and another 16 evenly spaced 70' radials in the due South to due West direction. My problem is that the distance from the Vertical to the property edge is only 40' in the East-South and West-North directions.

Am I better off adding more 70' radials into the longer quandrants and if so would this change the omnidirectional radiation of the vertical? Or should I add 40' radials into the missing quadrants?

Thanks for your advice

73 Jerry

I've had some success. I use four slinkies (two on each leg soldered end to end) and formed as an inverted V. It's a compromise antenna in every respect, but it does work in a limited space.

> Or should I add 40' radials into the missing quadrants?

I think you will be better of adding the shorter 40 foot radials in the missing quadrants. Otherwise, the oni pattern (in azimuth) that you hope to see will be distorted due to the missing NW and SE quadrants and the antenna efficiency is likely to be worsened (remembering that with a vertical like yours, the radiation resistance wants to be that apparent value of R in which all of the transmitted P appears to be dissipated - not the ground plane resistance itself. An inadequate ground plane increases the driving point impedance and lowers the radiation resistance - less ERP).

Pat

I do not have experience with the DX-LB but I just purchased the LB for use on 160, 80 and 60 meters. I will replace my G5RV Inverted V with the LB as an Inverted V. I spoke at length yesterday with Don at Alpha Delta about this antenna and he assured me that it should work well, equal to or better than the G5RV.

On the G5RV I have 125 countries worked on 80 and 25 countries on 160 even though the G5RV was not designed for 160. So, I expect the LB to be better since it is resonant on 160. I do use a wide range tuner, MFJ Versa Tuner II

And, 1.8 MHz x 3 = 5.4 MHz which is 60 meters. We all know that a 40 m antenna generally works on 3 x the freq = 21 MHz, so the same theory should be true for 160/60 meters.

Best Regards
Dan Schaaf

Haven't used the DX-LB+ but have the DX-CC. Works good for me. Only installation problem is they use solid core wire so it is a bit of a hassle to get straightened out.

Greetings Pat and the group,

I just replaced my Van Gordon dipole with a Alpha Delta DX-LB Plus.

It is without a doubt the best dipole I have every used. I have a
A3S beam that is pointed to Europe. On European stations I see about a
2-3 S-unit increase on the A3S and everywhere else the dipole is just
about the same as the A3S.

I am up about 25' and the only problem I have had with it was tuning
on 75 meters. I can get it down to about 1.5 at the top of the band
and lower towards the bottom. I just need to shorting it a little.
Not sure how much yet.

I don't think you will be disappointed. I love mine!

I would also recommend a horizontal delta loop. You could put up a full wave 80 meter loop if space was limited and run it as a long wire on 160. See Cebik's site http://www.cebik.com/content/a10/wire/horloop.html for more info. (You'll have to register, but it's free, and that site has TONS of information) At 40 feet, you'll get good performance. Mine is only at 30 feet and it does a fine job.

I have both. The Metal is very strong, very durable, and can be used as a verticle. The Fiberglas is lighter, but still very strong. Can be used as a vert but only as a support for a vert wire. You can easily support any type of field day antenna or wire with either one of them.

Unfortunately its the only part of the house that is actually solid. But I had an idea, you mentioned water pipes, unfortunately they are all plastic :S and all leak :) but I remembered we have a hole in the cellar wall that is big enough to get one of the smaller kids through, maybe the soil under the house may be suitable.

From: jerry
Topic: 5599 Message: 5606

I have five three metal and 2 fiberglass , the fiberglass has broken on me once with just a wire on it and i have managed to bend the metal when up at 40 feet but only in high wind and it is hard to even see , i prefer the metal have used one for at least 10 years and have a 25 ft section up now to hole one end of an inverted vee. you might do better in price looking on the internet or at some surplus sites , they sell rather high at hamfests the last one i saw went for 125 dollars and it was not complete but it still sold at seapac . complete ones with alll the goodies sell close to 200 hout here. i bought mine for about 100 ten years or so ago,

I am looking to get a military surplus antenna mast kit at the next
hamfest for field setup. The age old question, fiberglass or aluminum?

Hi Martin; you might want to look at MFJ artifical ground, if you don't have access to a metal cold water pipe or actual ground. With it you can take to your new house also.

Unfortunately its the only part of the house that is actually solid.
But I had an idea, you mentioned water pipes, unfortunately they are
all plastic :S and all leak :) but I remembered we have a hole in the
cellar wall that is big enough to get one of the smaller kids through,
maybe the soil under the house may be suitable.

5608. Re: 160 & 80m invert L / vert/ long wire/dipole etc etc

Yahoo group: ham-antennas (2008)
Date: 2008-08-23 18:22:57 UTC
From: Joe Oates
Topic: 5598 Message: 5608

I also have a small yard. I have an inverted L that consists of 3 - 30 foot Jackite telescoping poles that I run the wire up to the top. I go due south about 30 feet then turn 90 degrees and go due east for about 30 feet and then turn 90 degrees and go due north for about 30 feet, so it is in the shape of a "U". I have a counterpoise that runs directly underneath at about three feet above the ground. I feed it with coax to a 4:1 balun at the base of the closest Jackite pole.

I use an MFJ-993B auto tuner and it tunes 160 - 10. It is always 2-4 S units better on transmit and receive than an inverted V at 25 feet.

Hope this helps.

Regards,

Joe WO8J

Martin, look for a place where the telephone wiring is grounded. Older houses (with phones) had a solid wire from the phone box to a ground (like a metal pipe that was connected to the plastic piping). this was to make the water (a conductor of electricity) at ground potential, so if an electric water heater had a short in a heating element you would not get a shock.
Also the main electrical service has a mechanical ground somewhere that is connected to the breaker box or fuse panel, or it may be connected to a meter base outside.
i realize i am telling you about homes in the US, the UK may be a little different, as many overseas residences have three phase power into the home.
Maybe a little help or just to get you to think.

5611. Mobile antenna mount

Yahoo group: ham-antennas (2008)
Date: 2008-08-23 19:18:18 UTC
From: Dave Nathanson
Topic: 5611 Message: 5611

I need to find or create a mobile antenna mount that will automatically
& quickly avoid antenna breakage.

What I am thinking of is a mount with a hinge that allows the antenna to
flop backwards if an obstacle is hit (tree branch, garage doorway, etc).
Some sort of release mechanism would allow this to happen instantly
under pressure, but not unlatch due to wind resistance at highway speeds.

I'm OK with fabricating a mount but if it's already been done, and done
well, I'm also ok with buying one.

Has anyone here seen such a mount? Any ideas, suggestions or pointers to
existing products?
Thanks,
Dave

When the worst comes to worst lay out several pieces of wire around the edge as many as you can get down at least 6 if at all possible make some of them as long as possible and the others can be just a few feet (1meter) long and if you can get 12 or 16 down this way it should work well . I have also had good luck with chicken wire, poultry wire or similar if you can use it, but it might stain the concrete if it starts to really rust.

Hi,
could you recomend a decent tuner for such an antenna? Any experiences?
Manual or auto tuner?
Any info will be appreciated.
Thanks!

Some interesting antenna designs come up here, and I seem to like the one just presented by Joe. (the 3x3 160/80). It would fit my qth quite well and could be hidden during the day. Q. Would this work in a West-South-East leg pattern? I would really like to get to europe on 160. The qth is near Ann Arbor, Michigan.
Comments?

I have both. The honest vendors will tell you that past 30 feet you'll need aluminum, which is definitely the stronger material. We've had some crazy weather in the NorthEast this summer and both have stayed up, but the fiberglass mast is only at 25 feet (the aluminum is at 45 feet).

The other concern is UV damage. Aluminum is the choice for a permanent installation of any length. Some people claim success with painting the fiberglass masts to provide UV protection, but I couldn't be bothered. My fiberglass mast was only temporary while my roof got re-shingled, my aluminum mast will hopefully be up for a long while.

I don't have a suggestion for the hinge, but look at your kitchen cabinets, especially if they are the non-magnetic type, latches. You will see some that have a kind of pinching mechanism. I am sure that you could find them made out of a tough plastic. Then some kind of tethering and a hinge or spring mount and you should be in business.
Good Luck

I use a MFJ Versa Tuner II with mine and it works well, one thing I like is I can alter the antenna to work from 10 to 20 meters without to much trouble I shorten it and use a couple of wire ties to short the bits not in use and it gets it close to were it works without major returning say 2.5:1 and then trim it with the tuner.

At the price I think it might be worth looking at the MFJ even if I only use it at home.

For a ground for safety and static discharge, you need something that actually goes into the soil, e.g., one or more ground rods or pipes.

But a ground rod may do little good as an RF ground. For an RF ground (only), consider the MFJ artificial ground or several lengths of wire. But be aware that they will not ground your system for safety, or to discharge static.

5625. Marine mobile HF antenna....Suggestions requested

Yahoo group: ham-antennas (2008)
Date: 2008-08-24 23:38:13 UTC
From: soona4sail
Topic: 5625 Message: 5625

I am looking for suggestions for a simple 20 meter marine antenna, 100 watts max, for a sailboat. If anyone has had any experience, I would appreciate hearing about it. I don,t want to put insulators in the backstay as such, and I am tending to a (yuk) commercial mobile antenna, but would prefer to avoid that. Maybe I will just float a helium ballon (large, and haul up a longwire, or do a 1/4 wave oir 5/8 wave vertical.....
Anyway, any suggestions. I do have 100 feet of one inch wide grounding strap to trail in the ocean for a grounbd.,.
Thanks in advance 73 VE7MTW

5626. Re: [ham-antennas] Marine mobile HF antenna....Suggestions requested

From: James - KB7TBT
Topic: 5625 Message: 5626

Although the helium balloon sounds and would work great, it is not practical. I used to fly those suckers and the balloons are 300 to 500 bucks depending on the size and then you need about 150 to 200 bucks in helium, 15 to 25 mile hour gusts will lay the balloon down and pull your boat. The weight of the wire would also make the balloon lay down quicker. I would suggest using the mast for the sail and make a simple inverted V.

There is always the option of a mono band hamstick on top of the mast.

Of course it is going to depend on the size of your boat.

For something small you might look at using a buddistick or such mounted on the rear pulpit using one of the mounts designed to attach antennas to the rear view mirror mounts of a truck (Radio Shack). If you really just need just one band a hamstick or Hustler mobile antenna would do. Another solution in a similar vein would be to use an AH-4, SGC or similar remote tuner to tune a 102" whip, or shakespear fibreglass antenna.

But of course you'll get better performance if you can get an antenna higher and in the clear. If you have sufficient mast height you could add an auxilliary halyard (much like a flag halyard) and pull up the end of a Par End Fedz antenna. Pulled out of line from the mast this should give you decent performance, although it will undoubtedly intereact with the mast and rigging. These antennas are so good and so inexpensive this is certainly something I'd try.

A final solution might be to mount a screwdriver antenna on the mast head... grounded into the mast (ie mount it as most VHF antennas are). If you didn't want a permanent mounting you could probably design a mounting car which you would pull up the mast track, which would position the antenna clear of the mast and rigging when pulled aloft. Another way to do this would be to design a car to be pulled up the head stay. You'ld probably want to have a pretty big boat to keep that much weight and windage aloft permanently.

The boat I race has a kevlar backstay, so we can simply run a wire up the backstay when we want an antenna. We have a very thin "antenna halyard" going up to a turning block tied&taped near the top of the backstay. Wee mostly use this for an extended range cell phone antenna, so I don't have HF experience with this.

Two antennas met on a roof, fell in love and got married.
The ceremony wasn't much, but the reception was excellent.

hahaha an oldie but a goodie!

ok, now back to what you were doing!

5630. Re: [ham-antennas] Re: 80mtr vertical out od a silver rod

Yahoo group: ham-antennas (2008)
Date: 2008-08-25 21:16:08 UTC
From: Wayne
Topic: 5420 Message: 5630

First, I used to repair and sell CB's in the 70's and a bit in the 80's, and never heard of the "silver rod". Bear in mind this was in trhe USA, and not in GB or any other country.
Also bear in mind that there have been many different antennas, often using the same basic design.
Most all made claims to be the best antenna.
Did a fast Google search on cb antennas and then narrowed it to silver rod.
Basically a 5/8 wave antenna, evidently matched at the base. Also seems to claim a 4.2 DB gain, one even claimed DBd. Impossible gain factor for a 5/8 wave antenna, so is more good old CB'ers hype. More like 4.2 DBi as far as the gain goes.
Now, it is still a good basic antenna design, and most can be adapted to 10 meters.
Should be about 20 to 22 feet tall in stock CB configuration, depending in part on the "top hat" used.

For the record, most of the CB antennas gains claims were for DBi, and not DBd, and a good deal of difference between the two.

Now, it is not really practical at all to make one of this type of antenna work on 75 or 80 meters without some kind of loading coil. I have a junk antenna of similar type that I plan to see of I can get it set up for 10 or 12 meters, just need to figure a place for mounting it.

For 75 or 80 meters, one could use a fiberglas pole as you mention, and wind it helically, but it could be a lot of gueswork, trial an error. It needs to be electrically about 61 feet, more or less, depending on the portion of the band one wants to work.
Unless someone has already built a couple of them, it will be partly guess work.
And I don't think I want anything that tall as a free standing antenna around here. gets way too windy at times.
Not to mention that antennas about 9 feet or so are already made as mobile loded whips. Not the greatest for base use though.
YMMV

I have five three metal and 2 fiberglass , the fiberglass has broken on me once with just a wire on it and i have managed to bend the metal when up at 40 feet but only in high wind and it is hard to even see , i prefer the metal have used one for at least 10 years and have a 25 ft section up now to hole one end of an inverted vee. you might do better in price looking on the internet or at some surplus sites , they sell rather high at hamfests the last one i saw went for 125 dollars and it was not complete but it still sold at seapac . complete ones with alll the goodies sell close to 200 hout here. i bought mine for about 100 ten years or so ago,

From: Doug
Topic: 5632 Message: 5632

Hello group,

Please forgive what is probably a stupid question, but I can't find the answer anywhere else and thought you would be able to help. A friend of mine gave me about 400' of television coax, the good sturdy stuff that runs from the pole to the house. It's not marked but I think it is 75 ohm RG6. Can I use this as my transmission line from my TS-430 & TS-130SE to my main antenna? Will the mismatched impedance be a detriment to the rigs? Will performance suffer? Any and all help is greatly appreciated.

Cheers!
Doug...

5633. Re: [ham-antennas] Mobile antenna mount

From: Stan Labinsky Jr.
Topic: 5611 Message: 5633

Well, I normally don't advise the use of magnet mounts except for temporary needs. They do damage the paint in extended use and the cable flexing in the wind will make an unnatural polished mark in the finish over time as well. And let's not mention the rain leaks if the cable's not routed wisely into the passenger compartment. But for your needs, the magnet will plop over before anything breaks.

WARNING... personal gripe follows:
I positively dislike these Asian wonder whips that must be folded over! Something's wrong if you can't stick a good spring into the design.
Had one of those nasties (I call it my "George Jetson" antenna... which aggravatingly works really well) destroy the mount as it ripped it out of the roof of my van passing under a tree limb that I forgot was there.

But I install those mounts on school busses so I've had practice in repairing the sheet metal trauma. Just don't like asking for trouble!

And I cannot accept having to get out of the car and fold over the antenna while being drenched at the entrance to the parking garage, while the guy next in line honks his hooter and glares at me... for inconveniencing HIM! Yea! Right!
"Sorry honey... I know I'm dripping water all over the front seat, it'll dry. Well, yea, maybe it would be better to put the little antenna back on..." :-/

Not a good thing!

Subject: [ham-antennas] Mobile antenna mount

I need to find or create a mobile antenna mount that will automatically
& quickly avoid antenna breakage.

What I am thinking of is a mount with a hinge that allows the antenna to
flop backwards if an obstacle is hit (tree branch, garage doorway, etc).
Some sort of release mechanism would allow this to happen instantly
under pressure, but not unlatch due to wind resistance at highway speeds.

I'm OK with fabricating a mount but if it's already been done, and done
well, I'm also ok with buying one.

Has anyone here seen such a mount? Any ideas, suggestions or pointers to
existing products?
Thanks,
Dave

5635. Re: [ham-antennas] 75 ohm coax

Yahoo group: ham-antennas (2008)
Date: 2008-08-26 03:39:23 UTC
From: Andy
Topic: 5632 Message: 5635

In an ideal world, if you connected a perfect 50 ohm antenna on the end, your rig would see some impedance between 50 and 100 ohms, so the SWR would be no worse than 2:1.

If you connected a perfect 75 ohm antenna on the end, the SWR seen by the rig would be 1.5:1.

Neither is all that bad.

The impedance of the coax isn't what matters. It's the impedance seen looking into the coax, with the load connected at the end. And that might be anything. On average, this impedance will tend to differ from the ideal 50 ohms more than if you had used a 50 ohm coax, so the SWR will tend to be a little higher, on average. But it won't be higher in every situation ... in some cases it would actually be smaller with the RG-6 than with (say) RG-8.

Do you have any way of tuning your antenna and measuring the SWR at the rig? For best power transfer and maximum output from the rig, the SWR at the rig should be low, regardless of what cable you use.

As for loss in the coax itself, there are reasons why either 50 or 75 ohm coax might have more or less loss.

Andy

Hi Stan,

The main antenna for the time being will be two Opek HVT-400's in a dipole configuration with a 1:1 balun.

Andy,

I do have an antenna tuner and SWR meter, as well the antennae are tuneable, however I can't transmit and tune as I'm not licenced yet. I will be writing the exam this fall.

Cheers!

I like the Workman Hamsticks. They have a 3/8-24 coupler in the middle
to allow you to break them in half without affecting the tune.

If you use a mag mount you probably want a three or four 5" magnet unit.
What you may want to consider is installing a good heavy duty trunk
lip mount that you can just leave in place then you will have good
grounding and quick install. Remove the antenna and the mount is pretty
low key. That is what I do on the wife's mini-van.

Re: the guys who bent or broke these.

Did you have the guy rings set every four or five sections? They are supposed to be guyed and I was thinking about buying one of these setups myself so I'm curious as I was pondering going 60 feet with them.

From: Chris Moore
Topic: 5642 Message: 5642

Right ppl. I have a G5RV flat top which works well on my 10watts..

I put the Antenna analizer on it the other day to find it NOT resonant on any band what so ever...

Its a full size one so should it not be resonant on 40m or is it 20m ?

Have a go with yours guys lets get some results up here. Be nice to know what is the outcome...

My understanding was to guy them every 10 or 15 feet.

I have mine guyed on two levels for 45 feet and it's doing well. I didn't guy the very last 4 foot section (top). I figured the dipole would act as a partial guy for the top. If I had a non-wire antenna at the top I'd guy at the very top too.

Mine has survived a direct encounter with a wild microburst with very high wind, horizontal rain and hail.

5644. G5RV JR - build your own?

Yahoo group: ham-antennas (2008)
Date: 2008-08-26 17:18:36 UTC
From: SB
Topic: 5644 Message: 5644

I'm trying to find out if anyone has built thier own G5RV JR type antenna. I know it requires 450 ohm ladder line - would that mean I would need a 4:1 balun at the connection of my coax? If anyone has any plans or suggestions - please share.

5645. Re: [ham-antennas] G5RV Question....?

Topic: 5642 Message: 5645

Chris
The nature of the G5RV is such that it allows the use of many bands but is not particularly good on any of them. The reason why it requires so much coax form the balun is to minimize the SWR at the tuner. I found it to be unacceptable for my purposes and modified it using my antenna analyzer so that it was resonant on 40 meters, where I needed it the most. The result was the shortening of the horizontal section and cutting the ladder line differently.

Just a few days ago I modified it further by making it into the WT2T mini delta loop. I cut it for cw with the horizontal section about 98 feet and the descending sides 66 feet long. The 450 ohm window line was cut for a quarter wave on 7.025 MHz. The results are amazing with the swr on both 80 and 40 meters less than 1.4:1 at both the balun (4:1) and the the exciter. In fact the swr on 40 at the exciter hardly moved the needle on the Pro III and I made some nice DX contacts with it without using the external tuner.

I have the horizontal section up about 100 feet. If you have the ability to get the apex of the loop high enough you might consider this antenna. It tunes well on all the other bands although I do not need to on any other bands except the WARC bands.

A G5RV uses the ladder line a a impedance transformer. If it is
properly built the only balun required is a 1:1 current balun to block
common mode currents from the coax shield.

You need to say what kind of antenna you are thinking of using as it
changes the recommendations. A screwdriver antenna is the best mobile
tuner. ;)

5649. Ground radial installation question

Yahoo group: ham-antennas (2008)
Date: 2008-08-27 11:49:45 UTC
From: captain_magic
Topic: 5649 Message: 5649

I have an Outbacker Outreach 500 with the matching Outpost aluminum tripod. From reading other posts I see it's recommended I add at least three radials cut to a length matching at least the height on my vertical which is eleven feet.

Do I just lay these pieces of insulated wire spaced evenly on the ground under the three aluminum plates of the stand with both ends free, or do I attach one end of each wire to the stand with a bolt and nut??

Secondly, what guage of insulated wire is most commonly used?? I only have an Icom 756 that puts out 100 watts and I normally operate on 40 and 20 meters.

Thanks for anyones help.
Bob

Cheers for the info.

My G5RV is 53 feet each side a total of 106feet flat top and then it is
fed with 300ohm ribbon feeder (Window feeder) straight to a SO239.
You speak about a 4:1 balun. This is confusing to me !

5651. Re: [ham-antennas] Re: G5RV Question....?

I wouldn't worry about 4:1 balun. If the antenna works the way it is just continue on making contacts with the antenna. Thwe old saying "if it works don't fix it" seem very appropriate in the situation.

Chris,
When in doubt - check the source.
http://www.qsl.net/aa3px/g5rv.htm

Without knowing the actual length of your "feeder", your "G5RV" is center fed radiator, not true G5RV. Since "anything will radiate" you cannot objectively measure its performance without using some other reference "measuring stick".

PS You have not said anything about using a tunner.

5653. Induced Voltage

Yahoo group: ham-antennas (2008)
Date: 2008-08-29 03:31:39 UTC
From: Aaron
Topic: 5653 Message: 5653

Hi Everyone,

I have a unique problem that I could not find anything on when searching the archives. We live next to some high power transmission lines because of space limitations I could not put an inverted V out back so I put it out front with about half under the lines. I did not think it would be a problem as I had read on line that the Mythbusters TV show could not get more than a couple volts when trying to inductively couple to the lines and steal power. Well I was wrong and found about 300VAC induced on the antenna! I have not checked it with a scope but my DVM displays it in AC mode, almost nothing in DC. This does not bother me too much as I can cut the antenna down and it may fit the back yard. What does bother me is my BigIR 40-6m vertical which sits about 50ft from the lines. I checked it at 40M and found 30VAC on the coax center conductor. Fortunately from what I can tell this has not hurt my equipment but I don't think this is very good for it.

What I am investigating is some way to either block the AC with a high pass filter or short it to ground with an RF choke. Has anyone on the list ever come across a problem like this and what was done to resolve it.?

Thanks
-Aaron

From: Andy
Topic: 5653 Message: 5654

If you are measuring with a high impedance DVM then it may behave a little like static electricity ... lots of voltage but not much oomph behind it. With a sufficiently high impedance instrument, you can find almost any arbitrarily large voltage. How much does the voltage drop when you connect a 50 ohm (or even something like a 10K) resistor load? You might find that much of it goes away, because the source impedance of the voltage induced in the antenna is very large.

If so, just connecting it to your radio will similarly cut the voltage way down, without adding anything. But a choke would also do a good job of shorting it at 60 Hz.

Andy

Perhaps a vertical. I'd be worried about all the joints though.anything that was less than a good (perfect) conductor has the potential to become a diode and generate noise when you light it up with RF.

I'd be interested in hearing about any results you might have.

That works in principle but not in practice.

Unless the panels of the roof are well bonded together all you will end up with is random pieces of metal under the antenna not reactive at any frequency of interest. Remember the ground plane must be roughly a 1/4 wave dimension to be the effective other half of the vertical antenna. Bonding the panels together may be feasible depending on the construction and the condition of the roof. It may be easier to lay wire radials on the roof to form the effective ground plane.

If it were me, I'd try this setup in a heartbeat. Most vertical installations have 6-12 radials, at best. Although 120 is great, most have modest setups. Having an aluminum base would increase the efficiency tremendously.

This is not a debate about whether you agree, it is a question about what other hams would do. If it were me, I would place a vertical above it and have an efficient antenna.

My "actual" experience is different than that. I never bothered bonding the sheets in the roof of a metal building approximately 40 x 60 in dimension. at the top of the roof I placed two multiband verticals 1/4 wave apart on 40 meters. I then fed them in accordance with the recommendations of Hy-gain in order to make them switchable as phased verticals on 40 meters. The bases were mounted near the apex of the roof with the base of the verticals at about 8 inches from the metal roof.

Although it is hard to get the installation perfect without true phase detection, they did work as designed increasing the apparent directional gain characteristic when phased as end-fire antennas with a cardioid pattern and when phased as broadside with bow tie pattern. No effort was made to establish the ground plane other than as described except for a grounding set up near the exciter.

One time when I working for the local power company I was called out on a complaint that a resident near a local BC station was "hearing music" everytime she went into her garage. On investigating the problem we found that old joints in her aluminum garage roof were acting as a diode and she was getting signals through the aluminum roof. (We never did figure out how the roof acted as a speaker). We cured the problem by bonding each sheet of metal to a ground strap that ran around the roof and then to a ground rod driven close to the garage. That seemed to shut up the case of the talking garage.

From: ve3diz
Topic: 5664 Message: 5664

I hear a lot of talk about screwdriver antenna's and was wondering something about the difference between the different mobile hf antenna's. Is the coil on a screwdriver antenna just acting as a tuner for the whip or is it doing something more? And if it does just tune the whip, would it not be better to get a 102" whip and use an sgc 230 to tune it since it would give you a longer radiator? Is there anyone out there that can clarify things for me?

Hello Gentlemen,
I have an amateur friend that lives next door to a very QRO operator - when the large station next door powers "up" my friend can hear him through a metal parts box with plastic drawers filled with odd semi conductor devices - not always where he can understand him but always he can tell when he is, uh, QRO - Dave / N?ATH 73

Subject: [ham-antennas] Re: barn roof

One time when I working for the local power company I was called out on a complaint that a resident near a local BC station was "hearing music" everytime she went into her garage. On investigating the problem we found that old joints in her aluminum garage roof were acting as a diode and she was getting signals through the aluminum roof. (We never did figure out how the roof acted as a speaker). We cured the problem by bonding each sheet of metal to a ground strap that ran around the roof and then to a ground rod driven close to the garage. That seemed to shut up the case of the talking garage.

5666. RE: [ham-antennas] screwdriver vs. whip with tuner

Matt,

There is a vast difference between a tuned whip antenna and a screwdriver antenna.

The tuned whip forces the impedance of the whip to match the XCVR through the tuner.

A screwdriver antenna adjusts the antenna resonance by mechanically lengthening or shortening the antenna much like you would prune a dipole antenna for resonance. There are basically two types of screwdrive antennas, those that change the electrical length by changing physical length of the antenna, like High Sierra and Scorpion antennas, and those that change the electrical length of the antenna by moving a contactor INSIDE the coil, like the Hi-Q antennas.

There is a very definite difference between tuning a whip and resonating a screwdriver type antenna.

I encourage you to do some reading on each of these screwdrive type antennas. I think you will find the reading very interesting if not educational. After doing this reading myself, I settled on the Hi-Q 4/80 RT antenna for my HF mobile operations and I have not been disappointed.

Subject: [ham-antennas] screwdriver vs. whip with tuner

I hear a lot of talk about screwdriver antenna's and was wondering something about the difference between the different mobile hf antenna's. Is the coil on a screwdriver antenna just acting as a tuner for the

whip or is it doing something more? And if it does just tune the whip, would it not be better to get a 102" whip and use an sgc 230 to tune it since it would give you a longer radiator? Is there anyone out there that can clarify things for me?

I agree with what was posted re: the screwdriver antennas. I run a 102" whip and an SGC 237 on my Jeep, from 20m and up it works o.k., below that it tunes but is virtually a dummy load.

A screwdriver will outperform my setup handily. In comparisons on the air on 75m my setup is roughly an S3 and barely copiable, vs a friend's shortie Tarheel where he was an S9 with solid copy...both at 100W input. Another friend has a full sized screwdriver and he is well over S9, same distance, same power.

I chose the whip and tuner because the whip is a far lower profile vandalism target and that is an issue around here. If someone takes my whip I'm out $20 and not $550...but the performance I lost is rather large.

I really enjoy 40m and 75m and that leaves me pondering either a big coil Bug Catcher or going to a screwdriver after all as my tuner and whip is rather hopeless on those bands.

Andy,
Thanks for your input. I measured the current on the vertical and it was about 60uA. The V at 300V has 450uA. With the low input impedance the vertical is probably not a problem. I may play around with creating a low impedance path to ground for the 60Hz.

Hi Everyone,

OK name is Jack, call is VK4JRC. I generally only work HF, have a 30M HF APRS setup on my motorcycle, have field portable gear with Buddipole, tuners and other bits. I generally manage to radiate some signals, ocassionally :-)
BUT, I am wanting to build a half wave vertical for 20 metres.
I am looking to feed it with a gamma ring method, the same as the 11 metre antennas from the last millenium! The reason is, that I am in a high lightning strike area and need a DC ground antenna design.
I need the dimensions of the ring and the capacitance calculations for the feed point of this antenna. Anyone with ideas or links to where I may find out what I need to know?

The metal roof parts where they contacted each other would have been oxidized and created what we used to call a contact rectifier. That detected the strong RF signal, and the large roof acted as a sound board. A sort of simple crystal set. Neat.

Subject: [ham-antennas] Induced Voltage

Hi Everyone,

I have a unique problem that I could not find anything on when searching the archives. We live next to some high power transmission lines because of space limitations I could not put an inverted V out back so I put it out front with about half under the lines. I did not think it would be a problem as I had read on line that the Mythbusters TV show could not get more than a couple volts when trying to inductively couple to the lines and steal power. Well I was wrong and found about 300VAC induced on the antenna! I have not checked it with a scope but my DVM displays it in AC mode, almost nothing in DC. This does not bother me too much as I can cut the antenna down and it may fit the back yard. What does bother me is my BigIR 40-6m vertical which sits about 50ft from the lines. I checked it at 40M and found 30VAC on the coax center conductor. Fortunately from what I can tell this has not hurt my equipment but I don't think this is very good for it.

What I am investigating is some way to either block the AC with a high pass filter or short it to ground with an RF choke. Has anyone on the list ever come across a problem like this and what was done to resolve it.?

Thanks
-Aaron

I live in a 105 year old building in downtown Seattle made of Lath & Plaster so lots of wire mesh in the walls, live on the second floor of a four story building. I can't put up an outside (on the roof or in the tree) antennae for my 2 meter or 6/10 meter radios. What kind of ideas od antenna's are out there that I might be able to use? I am thinking a J Pole or maybe a dipole.

If you have any web sites great.

Hi Jack. A word about "DC grounded" antennas.
While it would seem a good idea, and for static dissipation it will work, that DC ground will, or should, appear as an open circuit at the frequency the antenna is designed to operate at.
The Ploy Phase company did a test years back in which they connected together the center conductor and shield of a length of coax and ran it to ground through some value resistor. At the other end they had a 50 ohm load across the cable and a dual trace scope set up, one input to the center conductor the other to the shield.
Then they put a pulse of current through the far end resistor and looked at what came through the cable.
The first pulse they saw was the one traveling over the outside of the coax shield, the second was the pulse being carried be the center conductor.
The point is... there was a difference in the time of arrival of the pulses even though the far end of the cable was hit by only one pulse. What this means is that an antenna which trumpets DC ground really more protects the antenna and the strike pulse coming down the cable will look like a real signal at the radio's input... a differential signal as opposed to a common mode one.
The repair for this phenomenon, caused by the cable's propagation delay, is to install lightning suppression in coax lead at the radio, and not just a spark gap, but a real suppresser... gas tube, capacitive coupled, etc.
This will happen even if the radio's chassis is solidly grounded to your ground rod system.
One other point. Your resonant antenna is like a tuning fork, in that it can be "rung" be the energy in a near-by strike and will "amplify" the induced pulse by its being resonant to the signal energy contained in the stroke at the frequency your radio is expecting to see.
These are not my words... check out Polyphaser.com (http://www.polyphaser.com/technical_notes.aspx) for the whole story.

Stan

Thanks Stan, Mmmm....food for thought, looks like the DC ground theory is not the total answer I thought it was. A lightning protection regime is still needed, lots of good info on that link.
Whilst I will still run with my half wave antenna project, I will pay attention to putting protection on my station equipment.

In the 70's I was Chief Engineer for WBRI, a three tower 5 KW AM station on 1500. When the station was first commissioned the antenna field was surrounded by cornfields. Around 1970 apartments were built in the surrounding cornfields. We had music coming out of toilets, sinks, refrigerators, and furnaces. A lot of grounding and strapping around discontinuities was involved. Since the station had a Bible format, urban legends abounded.

Hello group,

Keeping in the true interest of experimenting, has anyone tried adding a capacitance hat to the stinger (top adjustment rod) of an Outreach 500 just to see what it would do on 40 and 20 meters . . if anything??

I've read a few articles descrbing the fact that a capacitive top hat doesn't add anything to the energy transmitted, but in some cases, makes the vertical appear higher to fight trees and houses.

From: Tom
Topic: 5682 Message: 5682

Hello Hamtenna Group,

This post is off topic and not for the squeamish, as it involves guts, but no blood.

I had to replace a frozen relay in my built in antenna tuner. That happened when I tried to tune a tuner. While I was performing surgery on my rig, I decided to blow the cat hairs and dust out of it and clean the connectors by inserting all the connections a few times. The radio works great and had no leftover parts!

See: http://ph.groups.yahoo.com/group/ham-antennas/photos/view/f4ef?b=12

Cheers.

Hi Jack,

You're talking about the Cushcraft Ringo antennas (the AR10 and AR11 models). The 'Gamma Ring' was effectovely tapped inductor that put the antenna element at DC ground. They used a stub of coax to resonate the inductor, and the tap selected the correct transformation ratio. I can't help with the dimensions.

However, I built a 20m lambda/2 vertical (see http://www.geocities.com/bswadener/antennas/). Mine uses a homebrew tapped coil which wasn't difficult to make from 0.25" (6mm) OD soft copper tubing. I resonate it with an air variable capacitor with some padding across it (a stub of coax could be used instead). I used the program on http://www.smeter.net/antennas/vertune.php to calculate the optimal values. If you look closely at the photos on my page, you'll see that not only is the tap point adjustable, the coil length can be varied. In fact, everything is variable! hi An upside-down plastic planter pot protects the network from the weather. It works FB.

This groupy thing is sending messages to everyone in my groups also.
I don't think one from me has hit this group as I have gone into the
groupy thing and removed all my info. My suggestion, don't sign up for
groupy or you will be sending this stuff to all your groups to.

From: Aaron
Topic: 5653 Message: 5685

Hi Phil,
The vertical is and the V is as close as I can get it.

I checked the schematics on my tuner and there is an RF Choke bleeding the AC to ground. I connected the antenna and there was no voltage on the connection to the Radio. I guess the problem has been solved.

Thanks
-Aaron

This group is a phshing group they get all your contact info and spam
away. Even when you opt out of the group you get a message about false
rumors about them.

I am involved in a few different Yahoo groups and people have joined
just to get their message out then vanish from the group once they get
into the groups contacts. The only thing they post is their invite to
their group.

5688. Re: [ham-antennas] Re: barn roof

Yahoo group: ham-antennas (2008)
Date: 2008-09-01 11:04:13 UTC
From: Walter A. Breining
Topic: 5663 Message: 5688

Yes, it was 5 kW with 3 towers.

I also have been chief engineer at two stations that ran 250 W with 6 towers and one that ran 500 watts with 4 towers. The towers were phased to create a pattern with nulls to protect co-channel and adjacent channel stations that were on the air before us.

I held a First Class license in those days. We were all downgraded to a General Radiotelephone license later when we were combined with the Second Class licensees.

There are many more lower power AM stations than there are 50 kW stations. Many stations run as low as 250 w or less and many must cease operation, change antenna patterns, or go off the air during the night time hours. In the Midwest there are more co-channel and adjacent channel stations to protect because we have land with people and stations on all sides of us. You have oceans on the East and West of Florida.

Yes, there are a lot of strange stories connected with this RF problem. We were a Daytime only station as we had to go off the air at sunset to protect WLAC on 1510 in Nashville Tn. from our night time skywave. At least people could sleep nights.

I see that you are in Winter Park Fl. Here are some of the AM stations and their power levels in your area.

WPRD in Winter Park on 1440 kHz runs 5KW day/ 1 kW Night.
WDBO in Orlando on 580 kHz runs 5 kW both Day and night
WDSO in Sanford on 1400 kHz runs 1.0 kW. This was originally licensed as WTRR on 1400 at 250 watts.
The call WTRR is now used by a low power FM in Sanford.
WONQ in Oveido on 1030 kHz runs 45 kW Day /1.7 kW Night
WHOO in Kissimme on 1080 kHz runs 10 kW Day/ .190 kW (190w) night.
WDYZ in Orlando on 990 kHz runs 50 kW Day/ 14 kW Night.
WJCM in Sebring on 1050 kHz runs 1 kW Day/.011KW (011W) Night.

In the 70's I was Chief Engineer for WBRI, a three tower 5 KW AM station on 1500. When the station was first commissioned the antenna field was surrounded by cornfields. Around 1970 apartments were built in the surrounding cornfields. We had music coming out of toilets, sinks, refrigerators, and furnaces. A lot of grounding and strapping around discontinuities was involved. Since the station had a Bible format, urban legends abounded.

One time when I working for the local power company I was called out on a complaint that a resident near a local BC station was "hearing music" everytime
she went into her garage. On investigating the problem we found that old joints in her aluminum garage roof were acting as a diode and she was getting
signals through the aluminum roof. (We never did figure out how the roof acted
as a speaker). We cured the problem by bonding each sheet of metal to a ground strap that ran around the roof and then to a ground rod driven close to
the garage. That seemed to shut up the case of the talking garage.

Walter, thanks for the very interesting post. I love your last station entry:
WJCM in Sebring on 1050 kHz runs 1 kW Day/.011KW (011W)
That's great. AM broadcast's frequency does lend itself to that night time propagation, being just below the 160 meter ham band.I remember back in the 70's there were many low power "underground" stations on air, many colleges.
BTW I am in Winter Haven, not Winter Park, but that town really isn't far, more near Orlando. I'm about 50 miles south west of there. Cypress Gardens is in my town. Thanks for a good post.

Hello Gentlemen,
I hope I have came to the right place to ask - Is there a way to disassemble the TB-3 bearing? It is a used one I got with a tower I just purchased, and it has some rough spots in it. Can I press it apart? I have a press and I have the internal set screw removed but would rather use it a little (I think) rough than break it. Thought if I could get it apart and clean it up, maybe I could turn a new face on it in the lathe. Anyone been here before?

Dave / N?ATH

The only thing you can do is to use delete button. Rest of the task is left to the group owner/moderator who has to disable Grouply's access to the list archives. Once he does that Grouply people promise to stop their spam.

I have done it on a few groups among 25 that I moderate or own. Many more still to be done.

Regards
AB3EH Prasad

I vaguely recall when very low power AM nighttime operation started. These weren't pirate stations. It was for commercial stations that had to sign off at sundown; it gave them a way to stay on at least a few more hours. Presumably the QRP was necessary to protect co-channel stations that didn't go dark at night. Plate modulated transmitters aren't easily cranked down to such low power levels, so they ran their transmitters at full power, and inserted a pad ... essentially a 1KW or 5KW dummy load with a tap most of the way down ... between the transmitter and antenna system.

At the AM station where I worked, something in the shack containing the antenna tuner (matching circuit) at the base of one of the towers would "sing" with the audio we were broadcasting. We had to visit each tower to read a meter at its base, twice daily.

They were located in a swampy area. A few years later someone built apartment and office buildings around it. I heard stories about the construction workers getting RF burns, handling their steel beams (station was 50KW daytime). Shortly after, they moved the transmitter to another town.

That station even had some old (no longer used) open wire parallel feedline on glass insulators, running from the transmitter building part-way out to the towers. Remnants of pre-WWII days.

Ceramic dental fillings a must! I owned/operated a TV/radio repair shop for about 30 years staring in the late 1970's.
Lots of tube type TVs. They had tube high voltage circuitry that would radiate and light a neon voltage tester in my hand. Later years I read some article that a correlation was found between older Hams and TV repairmen from that era with cancers,eye problems,etc. I never really worried about it, since it was low freq RF,probably similar to the much used medical "diathermy" of the day. That was low freq RF directed in muscle tussues to induce a warming effect to treat sprains,stiffness, etc. Very common with osteopaths, chiropractors,etc. I'm 52 now and seem OK. Of course as solid state TVs came out the radiation was much reduced due to design of the lower voltage circuitry. Just reminicing...

Also when painting the towers.

Tower painters mostly have to be careful getting on and off the tower. They don't want to be the path between tower and ground.

I think the problem with the construction workers is they'd be touching two pieces of metal which were some distance apart and so had a significant RF voltage between them.

OTOH, you don't want to be climbing a tower and right next to FM or TV antennas, where the fields are much more concentrated. I bet they do turn them off (or switch to an auxiliary site) when changing lights on top of those towers. We always did.

Hasn't happened to me ... yet ...

Many of us transmitter operators spent our working days much closer than a wavelength from the antennas.

Well, many microwave ovens are around 1500 watts nd cook a chicken just fine. I realise the difference in frequencies here, but flesh is flesh,and didn't many TV transmitters operate in millions of watts?
What was that radio station in Cincinnatti area (not WKRP!) back in the 40's that was so powerful? Oh, it was WLW! 500KW. I found a link to this station's history with great photos:
http://www.oldradio.com/archives/stations/cinc/wlwpix.htm
My late shop partner said he could drive by the xmtr fiels and place a tin can to hie ear and heat the program!

While I had Tower climbers working on my cellular towers
if they would be close to the large 15.5 Db antennas I would
drop the site. The guys on the tower would start to get sick
if I did not turn off the transmitters ..
100 watts don't sound like much but when it is into a large
antenna it is a little different.

Did you have the transmission line such that you could switch the two in-and-out of phase so as to have the transmission lobes run either N/S or E/W depending on the phase?

My "actual" experience is different than that. I never bothered bonding the sheets in the roof of a metal building approximately 40 x 60 in dimension. at the top of the roof I placed two multiband verticals 1/4 wave apart on 40 meters. I then fed them in accordance with the recommendations of Hy-gain in order to make them switchable as phased verticals on 40 meters. The bases were mounted near the apex of the roof with the base of the verticals at about 8 inches from the metal roof.

Although it is hard to get the installation perfect without true phase detection, they did work as designed increasing the apparent directional gain characteristic when phased as end-fire antennas with a cardioid pattern and when phased as broadside with bow tie pattern. No effort was made to establish the ground plane other than as described except for a grounding set up near the exciter.

W8OKN said:

"I would place a vertical on top of it and enjoy the premium results of having a near perfectly efficient antenna."

That works in principle but not in practice.

Unless the panels of the roof are well bonded together all you will end up with is random pieces of metal under the antenna not reactive at any frequency of interest. Remember the ground plane must be roughly a 1/4 wave dimension to be the effective other half of the vertical antenna. Bonding the panels together may be feasible depending on the construction and the condition of the roof. It may be easier to lay wire radials on the roof to form the effective ground plane.

Here's the difference. At AM frequencies, say 1000KHz, our bodies are .006% of 1 wavelength. One wavelength being 984 feet approximately. At the lowest TV band, TV-channel 2 of 56 MHz, our bodies are close to a 1/4 wavelength. It gets worse. If the TV transmitter is operating on one of the UHF bands, then our bodies are several wavelengths long, and absorb higher amounts of the RF field.

I saw a demmonstration on utube once where the collage kids popped popcorn with their cell phones. If a cell phone with maybe 200 MW of power can do that kind of damage, what do you think a transmitter with an ERP of 100,000 watts can do?

I wonder if some of my health problems are because I spent many years in the transmitter shack when I was younger.

Yes, and cellular is at near microwave frequencies, no?
Back to the microwave oven/ chicken analogy!
UHF and up affects smaller things within the human body like eyes,and I suppose smaller organs, bones (inner ear bones affecting balance? hence nausea?). Just a thought. By "sick", did your workers feel nausea due to vertigo?

5708. Hello and J pole question

Yahoo group: ham-antennas (2008)
Date: 2008-09-02 19:13:09 UTC
From: Randy McKenzie
Topic: 5708 Message: 5708

Hello all,

Im KK4EJ, enjoying some mobile operations lately on a Yaesu 857 and home brew antennas. Lately been working on some designs to use at home and keep the XYL from exploding when she sees some long wire!

I work in the Communications Div of the Va State Police as a field tech, been there over 14 years. Im also a avid railfan and model railroader.

My question is about a J pole. Most I see have a half wave length, or close to it. Im curious is anyone has experiemented or seen any advantage of using a different length to get more gain?

Any input on what happens if you use a 5/8 wave length or even a 3/4?

My desire is to find something for 6 meter repeater that is rugged and easy to build. A little gain would really perk up my RX!

Thanks Bryan for the info and links, I just need to figure out that formula program and see what happens. As for the construction, I have already got the verical sections of aluminium etc and just need to make the feed for the antenna. I did also find a reference in a book I have here " The Radio Amateur Antenna Handbook" by William Orr W6SAI & Stuart Cowan W2LX, this book details a single turn Gamma Ring feed, which is what I was originally looking for. Anyway, your iteration of this design looks good too, so I might try it and see how I go.

From: Rich Schmuke
Topic: 5711 Message: 5711

I made a 20m vert , 8 wires forming a 4 ¾☐ dia cage, eight radials . The feed center is 20ft off the ground for operation , now about 6 ft for test setup. The 8 vertical elements are 16☐ 6☐ , I put it up and it has a good SWR around 11 Mhz , I started to trim a little to see what happens , now about 16☐ short and getting into the high end of the 20M band. I am looking for a wideband vertical to work to bottom of SSB and PSK31. Has anyone else has strange things with a cage????

KD0ZZ , Rich

I am not getting older but having a propagation problem with the neurons in the grey matter.

Any errors in spelling or facts are tramsmission errors

5712. 20 m Cage Update

Yahoo group: ham-antennas (2008)
Date: 2008-09-02 23:43:52 UTC
From: Rich Schmuke
Topic: 5712 Message: 5712

Ok , I now have good SWR , between 14.05 and 14.33, it is 1.2 , above or below these frequencies it will rise slowly. The 8 radials are cut each one a little different but correct length for the working frequencies range. The main vertical element is 8 wires forming a cage 4.5" in Dia but only 13' 4" tall. Any one got any ideas on why???

I need to reset the spacers for the wires and would like to just do it one more time before I epoxy the spacers.

I missed the first part of this thread so I would like some particulars. Is the feedpoint and/or radials elevated?

A " thick" radiator will be shorter than the formula will dictate. My 30M vertical was almost a foot shorter than calculated when I used an Aluminum Extrusion as the radiator. It was (and will be again) ground mounted over an extensive radial system made of 1 mile of aluminum electric fence wire.

5714. Hy-Gain 18AVT Vertical - Radials vs. No Radials

Yahoo group: ham-antennas (2008)
Date: 2008-09-03 00:42:12 UTC
From: Mark Saunders, KJ7BS
Topic: 5714 Message: 5714

Is anyone using the Hy-Gain 18AVT (NOT the 18AVQ or 18AVQII) vertical ground mounted WITHOUT radials?

I don't need lectures about using a vertical, ground mounted or otherwise, without radials as I've heard it all and read it before.

I am interested in ACTUAL results from those who have this antenna without radials, or that added them later. I am writing an article about this antenna and want some real-world insight to operating this antenna without radials. I already have lots of testimonials about using it with radials.

I welcome responses from those who tried without radials and later added radials as well.

I do not mean to sound abrasive, so please do not mis-interpret my tone.

Why would you write a scientific article based on opinion over using proven science? People who use this antenna without radials may make contacts, but the science proves that radials are needed and improve efficiency.

If you want your article to have credibility, wouldn't you use science?

Date: 2008-09-03 01:52:56 UTC
From: Rich Schmuke
Topic: 5712 Message: 5716

Sorry about the lack of information in the second post , the feed point is 20 ft during operation, 6' at test set up , 8 radials to be adjusted to 50 ohms at operation position. 5 turn RG-8X choke at the feed point. The vertical element is 4 1/2 " in dia and the now is about 2 ft shorter than a normal wire. Very wide banded , 14.05 to 14.33 @ 1.2:1 , it is mounted on a fiberglass pole with acrylic spacers to form the cage , polycarbonate spacers on the ends. I wanted to be able to work PSK31 and the lower part of SSB, it looks good with the analyzer but I questioned how short it is.

Subject: [ham-antennas] 20 m Cage Update

Ok , I now have good SWR , between 14.05 and 14.33, it is 1.2 , above or below these frequencies it will rise slowly. The 8 radials are cut each one a little different but correct length for the working frequencies range. The main vertical element is 8 wires forming a cage 4.5" in Dia but only 13' 4" tall. Any one got any ideas on why???

I need to reset the spacers for the wires and would like to just do it one more time before I epoxy the spacers.

5717. RE: [ham-antennas] Hy-Gain 18AVT Vertical - Radials vs. No Radials

Yahoo group: ham-antennas (2008)
Date: 2008-09-03 04:09:07 UTC
From: Mark Saunders, KJ7BS
Topic: 5714 Message: 5717

Thanks for your concern.

Don't assume I'm not going to use the science behind ground mounted verticals with/without radials, I am.

The science will be in the article, but what I want now is actual experience from hams who put up these ground mounted vertical antennas which state "no ground radials required". I want to include their experiences and the perceived improvement once a few radials were added and a lot of radials added.

Another thing I will be looking for, but have not gotten there yet, is information from hams who ground mount a vertical where they cannot get a 360 degree radial field laid down. What are their actual experiences when say only a 90 degree, 180 degree, or 270 degree radial field is used?

We've all seen the academics, the antenna models, read the radial/no-radial reports, read no-radial propaganda from antenna manufacturers, but what we've not seen is a comprehensive actual experience report radials vs no-radials vs partial radial field vs short radials vs resonate radials for ground mounted verticals. That is what I am after at this point, actual experience, and perceived performance. Believe it or not, there are hams who only have a yard the size of most two-car garages in which to put an antenna for ham radio and do not have room for a dipole, tower and beam, loop, or a radial field for a ground mounted vertical..

I do not mean to sound abrasive, so please do not mis-interpret my tone.

Why would you write a scientific article based on opinion over using proven science? People who use this antenna without radials may make contacts, but the science proves that radials are needed and improve efficiency.

If you want your article to have credibility, wouldn't you use science?

RF does not cause Leukemia or any other ailments except the immediate tissue burning if one gets in contact with too high of RF wattage.

I used to go onto towers radiating anywhere from 250 watts to 50 kW with no ill effects. I used to spend hours day after day point blank in these RF fields.

That was 30 years ago. I am now 59 and I am sorry but I don't think you will be getting rid of me soon.

When the wavelength approaches the length of the human body, the heating effect may increase. RF is magnetic energy not Gamma radiation.

The yuppies can take off the tin foil suits now.

> WJCM in Sebring on 1050 kHz runs 1 kW Day/.011KW (011W)

I vaguely recall when very low power AM nighttime operation started. These weren't pirate stations. It was for commercial stations that had to sign off at sundown; it gave them a way to stay on at least a few more hours. Presumably the QRP was necessary to protect co-channel stations that didn't

go dark at night. Plate modulated transmitters aren't easily cranked down to such low power levels, so they ran their transmitters at full power, and inserted a pad ... essentially a 1KW or 5KW dummy load with a tap most of the way down ... between the transmitter and antenna system.

At the AM station where I worked, something in the shack containing the antenna tuner (matching circuit) at the base of one of the towers would "sing" with the audio we were broadcasting. We had to visit each tower to read a meter at its base, twice daily.

They were located in a swampy area. A few years later someone built apartment and office buildings around it. I heard stories about the construction workers getting RF burns, handling their steel beams (station was 50KW daytime). Shortly after, they moved the transmitter to another town.

That station even had some old (no longer used) open wire parallel feedline on glass insulators, running from the transmitter building part-way out to the towers. Remnants of pre-WWII days.

Andy

Subject: [ham-antennas] Hello and J pole question

Hello all,

Im KK4EJ, enjoying some mobile operations lately on a Yaesu 857 and home brew antennas. Lately been working on some designs to use at home and keep the XYL from exploding when she sees some long wire!

I work in the Communications Div of the Va State Police as a field tech, been there over 14 years. Im also a avid railfan and model railroader.

My question is about a J pole. Most I see have a half wave length, or close to it. Im curious is anyone has experiemented or seen any advantage of using a different length to get more gain?

Any input on what happens if you use a 5/8 wave length or even a 3/4?

My desire is to find something for 6 meter repeater that is rugged and easy to build. A little gain would really perk up my RX!

Nice .. haven't seen that one yet .. but i am still looking for a picture thats alot closer to the counterpoise.

I already have the PDF manual from MFJ. The mechanical drawing is different than what the PCB is.

5724. RF Ground for HF 10-80m

Yahoo group: ham-antennas (2008)
Date: 2008-09-03 13:37:21 UTC
From: Jerry Stern
Topic: 5663 Message: 5724

Hi Group,

What do folks do when they cannot get an RF ground (not DC) within 8' -11 ' or less as recommended to avoid a 1/4 wave high impedance for 10m -15m ?? This seems like an impossibility unless you literally can have a "Shack" on ground level with your rigs against a a wall facing a backyard. As I understand the two main issues are if your station ground is 1/4 wave or odd-multiple (3/4,5/4, etc) then you have an high RF impedance to ground (= ungrounded situation) and you risk (1) RF voltage/current in the shack, eg on mics, rigs, etc and (2) your ground wire will radiate and become part of your antenna system, ie RFI, etc.

In the articles I read, it seems that the above issues were always discussed in the context of a dipole or beam antenna system. I have a ground mounted 43' vertical (no traps) with an extensive radial field of sixty radials each 70' long. The vertical is fed via a 100' low-loss coax. All the gear in the shack (including PC, Cable modem, etc) go to a single common ground point. My station common DC ground point goes to earth ground via 50' ground strap (and the earth ground is bonded to the center of the radial field via another ground rod).

Now for my questions:
1) Why would any RF signal from my HF rigs remain "ungrounded" or want to radiate HF RF through a high impedance 50' ground strap when there is a much much lower impedance path to the Vertical radial field?
2) with a single common ground point in the shack why would you still need isolators between the equipment to prevent ground loops between the equipment?

Tnx

For my two cents: they use to say (tongue in cheek) that one good anecdotal story was better than 10 scientific studies hihi. Sometimes practice and theory may be far apart and so getting hands-on feedback can be appreciated. But I think you would need a very, very large database of testimonials to take into account the huge differences in soil/earth conditions alone between radial-less sites to get a real semi-quantitative sense of what can be achieved without radials.

Mind you this is only my opinion ...

IMO, you mostly only need to worry about an RF ground *at* the feedpoint of an antenna that uses ground as its "other" half, such as a vertical. And you provide that by way of either an elevated counterpoise, or a ground radial system. And you connect to it right at the antenna's feedpoint.

Think of where the currents are going. The only place the RF current should go into the "ground", is where your coax feedline connects to it at the (vertical) antenna's feedpoint. Period. There should be no RF current taking a different path out of your shack. You want all of your RF power to stay inside the coax to the antenna. If some of the current takes another path to ground, then not all of your RF power is in the coax where it should be.

If you have a beam or other antenna that doesn't use ground as one of its radiating elements, then there is no RF current path to ground, so in theory (and often in practice), you don't even need to provide an RF ground. If hot spots and RF-in-the-shack become a problem with such antennas, then perhaps it is lack of a balun where one should have been used, to keep RF currents off the outside of the coax and keep your feedline from radiating.

If you have a vertical, then you kinda want to not provide extra paths to RF ground, other than the intended one: out the coax to the radial system at the base of the vertical. Other connections to ground may be OK, but you don't want the RF output of your rig to be taking those paths. Unfortunately, sometimes it is impossible to enforce that, and then things may get interesting.

> 1) Why would any RF signal from my HF rigs remain "ungrounded" or want to
> radiate HF RF through a high impedance 50' ground strap when there is a
> much
> much lower impedance path to the Vertical radial field?

There is a mantra that some RF engineers use: there is no such thing as "ground." Therefore, everything is "ungrounded." And that no two "ground" points will have the same potential, even two points on the same chassis, though I suppose that is less true at 80m than at higher frequencies.

How do you know your 50' ground strap is "high impedance"? Perhaps you are thinking how fat the strap is. But inductive impedance is determined by many other factors, including the loop formed between that strap and whatever other path is nearby. What is the whole path, out-and-back, that this current takes?

If the strap happens to be a quarter wavelength long, or a multiple, then interesting things happen....

Given a choice between available paths, electricity rarely decides to take *only* the best (i.e., shortest, or lowest impedance) path. Electricity splits between all available paths; so even the "high impedance" path may carry some current, as long as there is a voltage (DC) or an electromagnetic field (RF) that would cause that current.

Sorry, I have given you more questions than answers....

Andy

Thanks Andy,

So if I read you correctly, in my situation I guess my next question should be why should I bother with the extra 50' ground path at all provided all the rigs are DC grounded via the home electrical?

Thanks Bryan for the info and links, I just need to figure out that formula program and see what happens. As for the construction, I have already got the verical sections of aluminium etc and just need to make the feed for the antenna. I did also find a reference in a book I have here " The Radio Amateur Antenna Handbook" by William Orr W6SAI & Stuart Cowan W2LX, this book details a single turn Gamma Ring feed, which is what I was originally looking for. Anyway, your iteration of this design looks good too, so I might try it and see how I go.

5730. 160m dipole

Yahoo group: ham-antennas (2008)
Date: 2008-09-04 18:51:45 UTC
From: peglegkd5gyg
Topic: 5730 Message: 5730

I am wanting to get on 160m but don't have an antenna that will tune to 160. I have limited space and limited funds so i have to do it cheap. I was thinking of building a plain old dipole and trying to get it as high as I can in sort of an inverted V fashion. But i will only be able to get it up about 30 feet or so. I will then have top run the ends out to about 8 foot off the ground and the run the rest of the wire somewhere. maybe horizontal or out and then back up in another direction. Is an antenna like this going to work well enough to justify time and expense.

Also had another ideal, don't know if this would work, but to make it fit to my space in an inverted v form, would be some where in the middle or towards the end is place a piece of pvc and wrap wire around it to shorten up the length some but still have the correct length of wire. If this would work how far from the end should i put the pvc to wrap the wire?

thanks
chris

From: Dan Schaaf
Topic: 5730 Message: 5731

In order to use a trap or loaded dipole as inverted V, 30 ft high at the feedpoint has worked for me. Don't expect spectacular results but it will get you on 160. I use the Alpha Delta DX-LB as an inverted V at 30 ft height at the feedpoint. It is 100 ft long and the ends are 8 ft high. I have 26 countries on it since last Sept including VP6DX. It is somewhat omnidirectional like a vertical but the angle of radiation is not low like a vertical.

Best Regards
Dan Schaaf

Chris,
I have very limited space as well. I use an "inverted L" that resembles an end-fed "inverted V". The feed point is at ground level using a matching coil formed from 1/4" copper tubing. I have a bunch of varying length radials that cover an arc of about 180 degrees from the feed point area. The antenna wire then goes up about six feet then angles up to my tower (about 25 feet away) at about 35 feet. Then the wire angles down to about 18 feet off the ground and is anchored (using an insulator, of course) to a tree. The overall length, due to the effect of the shunt matching coil is about 118 feet. Using an "L" network coupler in the shack I can cover the entire band (with 30 meters as a bonus). The antenna resonates at about 1.850 MHz. I have worked stations from KH6-land to the east coast from here in California. Hope this gives you an idea.

73,
Troy, W6HV

5733. ATAS 120 on patio roof

Yahoo group: ham-antennas (2008)
Date: 2008-09-04 20:59:01 UTC
From: ke5voz
Topic: 5733 Message: 5733

I was thinking of putting my atas 120 in the center of my patio cover
which I belive i galvanized steel, sitting on the ground, with about 6'
steel stakes driven into the ground holding it in place.
How do you think it will work. Will the roof act as a goundplane?
Need to run about 150' coax, What would you use?
Any and all ideas will be helpful.

Thanks Art

For 160, and 80 meters I use a full size 80 meter dipole with an RF choke made with 1 1/2" PVC pipe about 9" long if I remember right (I would have to go outside and measure it for you if you are interested) wound with #18 wire that fills about 7 1/2" of the form. Then there is 15 more feet of wire on the end. If I remember right, the total length of each leg is about 80 feet. Mine is centered on 1840 and my antenna tuner makes it work from 1805 to around 1880.

Let me know if you want any more details and I will get them for you. I am scheduled for antenna maintenance soon anyway. Winter is coming.

Well. Lets say you erect a square wire antenna, and each side is one quarter wave,so it's a full wave in all. If you break the wire at the middle of the top or bottom (and insert a transmission line feed), it will be horizontal polarization.
If you break the wire mid point on either side it will be vert. polorized. Break it at either corner and it will be a combination V and H polarization. If you have multiple turns,I would think it would exibit circular polarization,as hams have done for years for ,say, a moon bounce (EME) because there is no way of knowing what the polarization of a bounced signal will be when it hits an antenna pointed skyward at that satillite.(or moon).
I think my answer is accurate,but hope I addressed your question.
Thanks,

> be why should I bother with the extra 50' ground path at all provided all
> the rigs are DC grounded via the home electrical?

Well, that's the $50,000 question. Not necessarily. If there's RF current through that 50' ground strap, the question is, what's causing it?

Electromagnetic (E-M) fields exist because of currents on wires. Currents on wires exist because of E-M fields. Which one is the cause? Will cutting the wire stop the unintended radiation, or will it only move the current to somewhere else? Or cause hot spots and the potential for RF burns?

Run coax from an amp to a dummy load, and all of the RF energy should be contained by the coax and go only to the load. No matter how many ground straps you connect to anywhere, none of them should carry any current and no radiation 'gets out.' That's how coax is supposed to work.

So when you replace the dummy load with an antenna, what's different? It's not easy to figure out. If there is something different about the load that can result in currents flowing back along the outside of the coax, you could try the brute force technique of a current balun (choke) to block it; and that *might* cut the path that feeds current into your 50' ground strap. (Or it might make things worse. It's best to understand a problem, if you can, before taking stabs at solutions.)

So I don't know ... I think I'm really not helping you at all!

Andy

Well we must consider the possibility of delicate DNA within our cells. We know cancers start with damaged (altered) DNA and go from there. I would assume strong EM radiation could certainly damage cells,so cancers are a possibility. I think many people react differently. Two can be exposed to a toxin,one gets cancer the other not. Who knows. Maybe red dye #2 is worse!

RF does not cause Leukemia or any other ailments except the immediate tissue burning if one gets in contact with too high of RF wattage.

I used to go onto towers radiating anywhere from 250 watts to 50 kW with no ill effects. I used to spend hours day after day point blank in these RF fields.

That was 30 years ago. I am now 59 and I am sorry but I don't think you will be getting rid of me soon.

When the wavelength approaches the length of the human body, the heating effect may increase. RF is magnetic energy not Gamma radiation.

The yuppies can take off the tin foil suits now.

> WJCM in Sebring on 1050 kHz runs 1 kW Day/.011KW (011W)

I vaguely recall when very low power AM nighttime operation started. These weren't pirate stations. It was for commercial stations that had to sign off at sundown; it gave them a way to stay on at least a few more hours. Presumably the QRP was necessary to protect co-channel stations that didn't go dark at night. Plate modulated transmitters aren't easily cranked down to such low power levels, so they ran their transmitters at full power, and inserted a pad ... essentially a 1KW or 5KW dummy load with a tap most of the way down ... between the transmitter and antenna system.

At the AM station where I worked, something in the shack containing the antenna tuner (matching circuit) at the base of one of the towers would "sing" with the audio we were broadcasting. We had to visit each tower to read a meter at its base, twice daily.

They were located in a swampy area. A few years later someone built apartment and office buildings around it. I heard stories about the construction workers getting RF burns, handling their steel beams (station was 50KW daytime). Shortly after, they moved the transmitter to another town.

That station even had some old (no longer used) open wire parallel feedline on glass insulators, running from the transmitter building part-way out to the towers. Remnants of pre-WWII days.

Andy

You're welcome, Jack. What may not be apparent in my vertical is
that the bottom section of tubing is around 5' (1.5m) tall. This
allows easy access, to adjust the length from the rooftop. I used
hose clamps that are 100% stainless steel (the cheap ones use a plain
steel screw). I applied a dab of antiseize compound to the hose
clamps to prevent the screws from galling.

Hello Hamtenna Group,

This post is off topic and not for the squeamish, as it involves guts, but no blood.

I had to replace a frozen relay in my built in antenna tuner. That happened when I tried to tune a tuner. While I was performing surgery on my rig, I decided to blow the cat hairs and dust out of it and clean the connectors by inserting all the connections a few times. The radio works great and had no leftover parts!

See: http://ph.groups.yahoo.com/group/ham-antennas/photos/view/f4ef?b=10

Cheers.

This involves frequencies much higher than HF. My comments were relating to things under 100 MHz.

At HF the human body is small compared to a wavelength. At higher frequencies, this is not true. Enough power at microwave frequencies can heat tissue. A common example is the microwave range. Perhaps some organs heat up sooner than others. Also cornea damage to the eyes has been reported at microwave frequencies, probably due to tissue heating.

Broadcasters have found that when climbers are near the bays for high power FM stations for an extended time, they often carry a fever for a day or so. It is common practice to turn off the transmitter or drastically reduce power when climbers are near the bays.

At AM stations in the 50's and prior, the DJ, announcer, or engineer would sit on one side of a window overlooking the transmitter. Early transmitters were built on frames with no significant metal shielding around them. The same for the phaser. (The phaser is the device that distributes the RF power to the towers in a multi tower array. It provides adjustment of the currents and phases to each tower.)

These people sat there for hours daily for years. One such set up was still at WOWO in the 70's as a back up transmitter. They used it a lot too. Their main transmitter was an Ampliphase. (Awfulphase) The slightest change in antenna impedance messed with the linearity. You just can't keep most multi tower arrays stable enough for such a transmitter scheme.

So I don't worry about near proximity to RF unless the frequency is well above 50 MHz and the power is more than a few watts.

While I had Tower climbers working on my cellular towers
if they would be close to the large 15.5 Db antennas I would
drop the site. The guys on the tower would start to get sick
if I did not turn off the transmitters ..
100 watts don't sound like much but when it is into a large
antenna it is a little different.

5743. G5RV comes in various sizes?

Yahoo group: ham-antennas (2008)
Date: 2008-09-05 14:37:53 UTC
From: SB
Topic: 5743 Message: 5743

Well after reading about the G5RV - I went searching for an ideal price. Instead I got all different sizes. Seems the G5RV is typically 102 feet and the junior version is around 50 feet.. less the 80m for the junior version. Now on Ebay there is a 60 foot one for 80 to 10m? And a whole bunch of other sizes - are these just copies? I'm lost here - can someone share their experience with this antenna. I have only 50 feet to play with. No room for a vertical and the G5RV would be ideal for 40m & 20m + 15m. I will be using a ground plane for 10m.

From: Chris
Topic: 5743 Message: 5744

In a nutshell, the 102' version is the minimum length to be even a bit efficient on 75m. So if you are interested in operating there and have the room, don't buy a shorter version.

If you have the room, longer is better.

Price shopping them isn't the wise choice. You would be much better served looking for the ones with a high quality construction instead or making your own out of quality components.

There isn't a whole lot to a G5RV, the measurements and specs are all over the place and skimping on quality for an antenna makes no sense at all, may as well not bother putting it up.

Yet another .02. I would recommend you look at the "Carolina Windom" which is an off-center fed dipole with a 4:1 balun at the feedpoint. I find them simpler for people to install properly and generally better performers than a G5RV for multi band use. Someone like http://www.buxcomm.com/ who makes quality wire antennas is recommended over the cheapest you can find on ebay.

I can only tell you about the full sized version as that is what I have
as my camp site antenna. It is a fairly good radiator, but you do need
to use an antenna tuner. I use mine in an inverted Vee configuration
with a mast at the center up 35 feet and the ends tied off to whatever
is convenient at various camp sites we have visited in the RV. Mine is
100 feet long.

I had the one 65' one that has loading coils in it and is sold on ebay. It is now sitting in a box. I didn't find it a particularly good radiator and had trouble with RF in the shack with it even running a current balun were it connected to coax. I finally pulled it down and put up Alpha Delta DX-CC. Much better antenna but higher cost. If you only want 40M and with the size you have to play with, you should look at the Alpha Delta DX-EE. Only 40' long and does 10-15-20-40. If you can get out to 82' by doing inverted V and maybe letting the ends droop some you could use a DX-CC which add 80M. IMO the best thing to do with the shortened G5RV is avoid them. They take a mediocre design and make it worse.

Ah yes, the Ampliphase. The chief engineer at one station where I worked said his predecessor installed it, but could never get it to work right. It gave them nothing but trouble. RCA's instructions were fine until you applied modulation. The new CE figured out how to deviate from RCA's instructions and make it moderately stable. Many things did cause havoc with its adjustments, but remarkably the tide was not one of them (it was in a tidal marsh).

> At AM stations in the 50's and prior, the DJ, announcer, or engineer would
> sit on one side of a window overlooking the transmitter.

Many stations did this well past the 50's. I would have said that some still do ... but are there any AM stations left with a live DJ? In the same state as the transmitter?

Actually, I visited one of my old employers a few years ago, and they still had a DJ about 10' from the AM and FM transmitters, in a wooden building, within the circumference of the guy wires. They may be the exception. And one of the last times I listened, they still had the same morning DJ as they did since before I was born.

From: w8okn@charter.net
Topic: 5743 Message: 5748

The G5RV is not much different than a regular dipole. In fact, a dipole has two radiators, giving it the name, "di"pole. The G5RV may have a vertical component, but certainly not worth mentioning. I'd go with a ladder line fed dipole ANY day over a G5RV.

The G5RV is past its prime. It was intended to originally be used as a means to match a dipole to a tube type output transmitter. The SWR was moderate for a tube output rig, close enough so that ham did not need to always use a tuner. It is simply not low enough for today's rigs. Thus, a tuner is required, which defeats the entire original purpose of the G5RV.

If you want more power to go to the elements, then use the longest dipole, over 100 feet for efficiency and better matching on the lower frequencies, and run ladder line to it. Since you are going to be using a tuner regardless, you may as well get as much power to the antenna as you can.

From: Randy McKenzie
Topic: 5743 Message: 5749

Seems like every antenna will have fans and enemies. Ive talked to several hams who use the G5RV and really like the ability to build it themself, tune it on almost any band and not have a yard full of wires. They used ladder line and a tuner, and operated fine. Others you will find will complain about it and make claims of every sort and size.

I built one using 64' legs and it tuned up fine, tho I was limited in the height and length, requiring me to make a few bends in the run. I made contacts on it and it worked even in a cramped yard and a house with a metal roof.

My suggestion is build one and try it out. A little wire and some ladder lead and see what it does for you.

If us hams ever have one antenna that fits perfectly and everyone loves it its time to turn in the license and watch tv!

wanna stir up a good fuss? Talk about how good a verticle is on HF with no ground radials.....stand back!!!!!

From: Bill
Topic: 5743 Message: 5750

I have used a modified version of the G5RV at a length of 98 feet on 40 very successfully. I is not a very good antenna but with the mod it worked well on 40. I recently decided to replace it with a super loop. You can find the dimensions of the super loop by googling it. It is about the same overall length as the G5RV.

The G5RV is a very inferior antenna for a variety of reasons. In particular the feedpoint impedance is so bad that it requires a long length of coax to reduce the feedpoint swr. The super loop on the other hand works well on both 80 and 40. I have modeled it using EZNEC and the theoretical characteristics re very close to the actual characteristics I have observed. On 40 the designers claim 4 dBs of gain. EZNEC shows 8.64 dBi.

The designers claim that the super loop acts as a bisquare on 40 meters and a full wave loop on 80. The EZNEC plots on 80 are not all that good but the 40 meter plots look quite nice.

If you are interested I will post the dimensions I have used for mine.

I started with a G5RV with terrible results, switched over to an Alpha Delta DX-CC and am now having the time of my life on PSK. Only drawback is that it's slightly directional and can get most of Europe but not to the West Coast or the Pacific. It's mounted in an inverted fashion. Recommend it highly.
I live in the city and the lot is small but it worked out.

5754. advise please?

Yahoo group: ham-antennas (2008)
Date: 2008-09-05 23:45:08 UTC
From: Ken Snipes
Topic: 5743 Message: 5754

I have a old aluminum dipole for 10/11 meters , but the mount that it comes with has cracked and lost it's holding ability. So im going to re use the radials for a 10 meter dipole, but I wanted to ask, would it be better as a horizontal dipole, or a inverted V ?

once it goes up, im not looking to bring it back down anytime soon, so any advise would be great. It's going to be mounted for my workshop use, and ill be in there a lot , so I wanted a 10 meter ant that would be good for the DX thats supposed to be starting....

May be what they used to call a Trick Stick. I would run it horizontal. If possable, you might want to have a way to manually turn it 90 degrees. It will be a bit directional. If the ends droop a bit I wouldn't worry about it. If you do not use a balun, coil up about 4 turns of coax in a 4 inch diameter circle as a choke balun.

The old ARRL Handbooks and Antenna Handbooks use to have a 15 or 10 meter rotatable dipole that used aluminum tubing and a coil for matching, fed directly with 50ohm coax. Easy to make. I built one for 15 meters back in 1966(when I was a Novice), and worked a lot of dx with it, and used the armstrong method to turn it.
You might want to take a look at it and see if it could be what you are looking to do. Will save a lot of time.

You know what that "balancing network" on the far end is? It is a termination resistor. I think it is 100 Ohms. I had one when I lived in Rio Rancho, NM. We rented a house, and the property owner wouldn't let me put up a bunch of wire, so I got one of those and put it up. I could check into the local HF nets on 80 meters, but was ALWAYS one of the weaker stations. On 20 meters and up, it was like running an attenuator. By 10 meters it sort of began to work, but was still not a top performer.

If you want to put up something similar that actually works, mount a wire in this configuration, but don't terminate the ends. Use an automatic antenna tuner on the remote feed point. This what I wound up doing. It still was a soil warmer but on 80 meters I could at least be heard.

Yup, but I really think the add saying the military uses them is hype.
Someone who might have been in the military might have bought one and
had it shipped to a FPO somewhere and the sales dept jumped on it saying
"See, used by the military". What I would label as "deceptive"
advertising. Would really question if they bought a large quantity on a
GSA contract.

To bad, too, as B&W used to have a good reputation. They made a lot of
stuff home builders like myself used like preformed coils.

From: g.drummond
Topic: 5766 Message: 5766

Hello,

Does anyone know where I can find the wormgear clamps and tubing used to support the wire elements on the Lightning Bolt Quad antenna or know where to find parts to fabricate same? I have a Quad I would like to build but want to use the clamps/tubing system used on the Lightning Bolt since they are adjustable and durable.

Thanks & 73,
Garry - K4OR

Worm gear clamps can be purchased at any auto parts store.
Just make sure they say stainless steel on the package.
There are cheap versions that will rust out in no time stay away from those.

Topic: 5752 Message: 5768

I don't know the exact history of the T2FD antenna, but I think it really was developed under contract for the military / government.

Two reasons why the military likes them is because they don't need a lot of fuss, and they are broadband (and not just on our harmonically-related ham bands). I think B&W got in that business by being one of the government's suppliers of them, decades ago.

People like FEMA still use 'em, partly because they do ALE all over the HF band where you need a wideband antenna, and some power loss is acceptable.

The Rhombic antenna has a pretty good reputation, and it, too, uses terminating resistors. So don't knock them just on the basis of that.

The T2FD is more than a dummy load with some wire attached. It's more like a dipole with a resistor (600-900 ohms IIRC) on the far end that catches the energy the antenna didn't radiate; and its presence also might add to the current through the dipole (at frequencies where the current would otherwise be too low to be effective), and radiation comes from the current.

Would I want one? Doubtful. It doesn't take much work to make a more efficient antenna, if you know what frequency you're using. However, from what I hear, the inefficiency isn't so great to make them useless, maybe 2-6dB (an S-unit or less), though some claim it is more.

Andy

5770. Off-Center Fed Dipole and Balun question

Yahoo group: ham-antennas (2008)
Date: 2008-09-06 22:36:15 UTC
From: lecontejoe
Topic: 5770 Message: 5770

This is a long story, here's the short version.

Just built a new house and moved in. I can put up a 135-foot wire antenna -- but -- one end will be only 18-20 feet above ground, the other end will be 25-30 feet high.

I'm looking at putting up an off-center-fed dipole as shown in the ARRL Antenna Book, 1995, page 7-21.

135 feet of wire fed 45.3 feet from one end with coax through a 4:1 current balun. The Antenna Book says this will operate on even harmonics -- 3.5, 7, and 14 Mhz.

I can ground the rig and coax to the house electrical ground and to a separate ground rod that will be used only for the ham station. Running IC-735 at 100 watts max.

Anyone used an antenna like this?? What happened??

I'm planning on using a Unadilla 4:1 balun -- and suggestions or warnings??

Thanks.

Joe,

How wattage do you plan on putting into this antenna system? I melted a Unadilla balun real quick with about 550 Watts. If you are going to push any significant wattage into the antenna I suggest a DX Engineering balun.

if you are looking for heavier duty then what you will find in most
autoparts stores
check for truck parts suppliers or look in the phone book for stationary
generator
suppliers. not the generators you can buy in home depot, i'm talking
about ones
that generate 600kw and up. some names to look for are detroit diesel,
caterpillar,
and cummins.

5776. Re: [ham-antennas] multi turn loop

Yahoo group: ham-antennas (2008)
Date: 2008-09-07 05:25:05 UTC
From: Prasad Agrahar
Topic: 5763 Message: 5776

David

I am confused about loops. I dont get how you are using a 6 turn loop and where would you put a variable capacitor in it? How far away is the pickup loop positioned? I always thought that variable capacitors are used at the far end of single turn loops. Is your capacitor on the pickup loop? If multi-turn loop has no direct connection then how is it terminated?

I also understood that there would pretty high voltages at the capacitor making it necessary to use wide spaced capacitors and also operate at pretty low power (5W or so). People also told me that a radiating loops create a lot of RFI around.

Regards
Prasad

Thanks, Clint.

I just had an e-mail exchange with him and he has exactly the balun I need.

Now, the problem is antenna length.

I wanted to erect an OCFD for 80, 40,and 20 -- 136 feet long fed at 45.3 feet from one end. However, looks as though I can only get 125 feet of wire in the air. I may be bale to get 135 feet but the last 10 feet will have to be bent, drooped, or something other than horizontal.

So, I'm thinking now that I'll have to go with an OCFD for 40 and 20 -- 65.5 feet overall length fed at 21.6 feet.

I'll get out tomorrow, measure and think about it -- I really do not want to give up 80.

Thanks.

Let the last 5 feet on each end droop and it should still work ok.

Absolutely let the ends droop. The difference will be un-detectable.

Among the "goodies" and the "junk" I carefully saved when we moved is a balun that also has a lighting arrestor built in. Tubular with a "hanging ring" at one end and two wire terminals and a coax connector.

Label has disappeared. I was using it at the top of an inverted "V" for ten meters. Now I don't know if it was a 4:1 or a 1:1 balun. Any way to tell what it is?

From: lecontejoe
Topic: 5770 Message: 5784

Thanks to you two gents who offered suggestions on "let 'er droop."

This is a new house -- no trees on the lot -- house and detached garage have hip roofs, shed/workshop has a gable roof. I'm looking at securing one end of the antenna to one of the vent pipes coming out of the roof of the house and the other end to the gable end of the shed -- but that will get only about 95 feet. If I run the antenna from one vent pipe to another, turn 90 degrees and run to the shed I'll get 115-120 feet.

We moved in a month ago -- this week I'm sowing grass, tilling the garden, sowing a cover crop on the garden, emptying the mystery boxes in the garage so I can get both cars into the garage, and -- finally -- erecting the wire antenna. If all else fails, I'll put up a 40-20-10 mtr OCFD (68 or so feet long) but I'm shooting for 135 feet.

I'll let everyone know how it works out.

Plan to put 2 mtr/450 mhz verticals in the attic.

If you have a antenna anilizer or know some one who dose you can place a 50ohm resistor accross the screw terminals and mesure the impedance at the coax connector if it reads 50ohms it's a 1:1 if it reads 12.5ohms it's a 4:1

Pretty much. However, I suggest a little better method. Use a carbon composition resistor of 50 ohms to check for 1:1 at 20 Meters (a reasonable frequency) and a 200 ohm resistor for a 1:4. It is much easier, and more accurate, to check for a good match than to try and determine a 12.5 ohm value with reactances.

5787. Lighting Bolt Parts

Yahoo group: ham-antennas (2008)
Date: 2008-09-08 00:11:27 UTC
From: Garry
Topic: 5787 Message: 5787

Thanks to the two responses for this querry. I should have worded it differently. I have access to the worm gear clamps. I don't know what type of material was used that supported the wire elements where the elements were attached to the poles. It appeared to be two pieces of tubing where one wrapped around the worm clamp and also held the other tube the element wire ran through. This is mainly what I need to find. Does anyone know how to contact the former owner of Lightning Bolt Quads? I think he was associated with the auto industry.

Thanks,
Garry - K4OR

Ok i have them posted in the pictures section ... look for "MFJ-1798 issues" ....

The 2 meters portion is at highest 1.8:1 at 148Mhz ... iv almost given up trying to figure out why its that high ... (measured with a MFJ-259b and 150' of RG-8 mini X) the 70cm never ventures above 1.5:1
Might help if 1"OD aluminum tube was used instead of wood .. but i don't have any spare and i don't want to buy 5' when im going to use 3 - 4 inches !!!!

From: ash_lee52
Topic: 5770 Message: 5792

I use the Buckmaster OCF Dipole rigged as an inverted V... and it continues to outperform every other antenna I've tried except a YAGI. The Buckmaster has, I beleive, a 6:1 balun and legs of 45 and 90 feet. They specify that it should be hung with the top at 35 feet and the ends at 10 and 8 feet. So your set up should work great.

Have a look on eham.com to read all the glowing reviews of this antenna.

Nope, I have not, but there is very good phasing information in the Hy-gain manual .in the back of it.
Go to the Hy-gain page at this link and download the AV-18HT manual. it for one has phasing info.
Lots of other pages on the internet if you need others just let me know.

From: Bill
Topic: 5770 Message: 5795

Hi Joe, I run a similar setup to yours. I have a 735 running barefoot. I'm on a 1/2 acre lot and with my mast in its most convenient location I am limited on the short side to about 45ft or so. I built an OCFD with a homebrew balun. Originally used 14awg THNN for the elements. With the feed at 35ft and the ends at about 12ft (I've since raised the long end to about 20ft. Someone I know who has done a lot with these antennas said he's found them to work best with the long end close to the same height as the feed), the lengths came out to 85ft and 45ft to get <1.5:1 on 80 (75 with a tuner), 40, 20, 17, 12 and 10. Works pretty well on 75 for regional work, and reasonably well on 40 and into europe on 20. I've since switched the wire to 16awg enameled. Needed to make the long side a little longer, I'm assuming because of velocity factor difference. If this is your best choice for the space you're in, I think it would work fairly well for you. I get decent reports. The 735 seems to get some nice reports on audio, both with and without the compression.

The one thing I need to check at some point (maybe someone can help with this), I used a red 2" core for the balun that I assumed was a T200-2. 17 bifilar turns of 16awg enamel coated wire. I wanted to build another and bought the wireman kit (831) at a hamfest. When built to their plans I get 3:1 across the board (even when I used my wire and plans). What I haven't tried is different wire lengths with the wireman balun. Can a difference in cores affect impedance? I would think that's strictly a matter of windings. The core material, I would think, would affect freq response and bandwidth. Any thoughts?

(I seem to be good at the "long" version of a short story!)
Good luck with your project!

Suspect the trailer hitch mount is adequate, but not stellar.

As for which antenna is "best" -- well it depends on whether you have
size/weight restrictions, price restrictions, what band you want to
operate on, etc.

If price and size wasn't an option, I'd go with something from
<http://www.hiqantennas.com/>

I *think* from my reading that the distance between them is
significant depending on the band you are operating. Meaning if you
phase them for 40m the distance will not be ideal for 20m.

You would be better off phasing mono-band verticals from anything I've
found poking around various books and materials on phased verticals.

Topic: 5663 Message: 5800

>This is a car, and the only real option is a hitch

Hello,

Echoing the other email I would just like to add screwdriver antennas are nice because you don't have to swap antennas (think hamsticks) each time you want to change bands. Also look at high sierra antennas. The bigest concern is cost for screwdrivers over single band. Two hamsticks for 20m and 40m with a magmount under $100. A third option is a good old 102 inch whip with an good autotuner... All have pluses and minuses..

Humm Verticals.... I have a EVX6000 up at the moment due to the house has scafolding all over it and its not a touch on my G5RV... The windom is no better or no worse than the G5RV. I cant believe ppl still make these silly claims. At the most you will see is half a S point on ya signal meter. I have both and dont favour one from the other.

Totaly agree with the G5RV can be bent and still work well. A mate of mine has his running down his roof along the gutter down onto the top of a 6 foot fence and around the garden wall. IT STILL WORKS FINE... Have a look on DXZONE for antenna designs there are 1000s You may find just what ya want...

5802. Re: [ham-antennas] Re: G5RV comes in various sizes?

Yahoo group: ham-antennas (2008)
Date: 2008-09-08 14:54:39 UTC
From: Bill
Topic: 5743 Message: 5802

I must say Chris that the G5RV worked well for me but not until I modified it in the manner of the ZL design. I shortened it and recut the 450 ohm ladder line to make it more responsive on 40 meters. By doing so the intrinsic design flaw in the G5RV was eliminated. That flaw is that it requires a very long length of coax to ameliroate the bad feedpoint swr. As such it is a design that is intended to provied opportunities fo those with small sapce for an antenna at the cost of overall efficiency (taking into account the losses in the coax). While it works and I have used it, it was always with the understanding that it was a design with major compromises for those with limited height and space. I do not make any claims that it is better or worse than the windom since I have not used a windom since 1958.

I recently switched to the Super Loop which is no longer than the G5RV but requires more height bercause of the descending portion of the triangle. Both EZNEC and expreience are proving it to be a better antenna with the same overall length as the G5RV.

Humm Verticals.... I have a EVX6000 up at the moment due to the house has scafolding all over it and its not a touch on my G5RV... The windom is no better or no worse than the G5RV. I cant believe ppl still make these silly claims. At the most you will see is half a S point on ya signal meter. I have both and dont favour one from the other.

Totaly agree with the G5RV can be bent and still work well. A mate of mine has his running down his roof along the gutter down onto the top of a 6 foot fence and around the garden wall. IT STILL WORKS FINE... Have a look on DXZONE for antenna designs there are 1000s You may find just what ya want...

5803. Delighted with "Bi-Tri" - Gonna build another one

Yahoo group: ham-antennas (2008)
Date: 2008-09-08 15:05:49 UTC
From: William Trippett
Topic: 5803 Message: 5803

So far my experience with the "Super Loop" antenna has been fantastic. I used th 80-40 meter design and the no-tuner SWR on 40 is amazingly low. DX contacts have been very good as was the experience on the Russian RTTY test.

I built it using the MFJ Antenna Analyzer and EZNEC so the feedpoint impedance was designed to be 200 -j0. That made the match with the 4:1 balun a piece of cake.

Although the designers claim that on 40 meters it acts as a bi-square with 4 dB of gain (EZNEC suggests about 7.5dBi) I call it a "Bi-Tri" since it acts as two triangles fed by the balun (So does the regular bi-square of course except that the combination is a square instead of another triangle). The maximum gain according to EZNEC is 26 degrees on the vertical.

It also works well on 80 meters using the stub to make it a full wave antenna.

Since it is no more than 102 feet over all it fits in tight spaces but does require some height. Mine is up at aboput 85 feet in a couple of fir trees with the bottom at about 44 feet.

If anyone els has any experience with this antenna please post your comments.

I have everything I need including the spreaders. I have a Kirk Quad kit I bought back in the early 70's and never built. Their method of attaching the elements to the spreaders was to drill a hole through the spreader. I don't want to do this because you can't adjust it if need be without drilling additional holes. The Lightning Bolt method using the clamp/tubing method allows for adjustment of the element length if necessary. I'm just trying to find their clamps or find out how to make them.

Thanks,
Garry - K4OR

>
> Thanks to the two responses for this querry. I should have worded it
differently. I have access to the worm gear clamps. I don't know what
type of material was used that supported the wire elements where the
elements were attached to the poles. It appeared to be two pieces of
tubing where one wrapped around the worm clamp and also held the other
tube the element wire ran through. This is mainly what I need to find.
Does anyone know how to contact the former owner of Lightning Bolt
Quads? I think he was associated with the auto industry.

From: Don
Topic: 5807 Message: 5807

I am interested in using HF in a Kayak.
The boat is all plastic so no ground plane.
Could I use a trailing wire supported by floats?
Let's say the wire is 125ft long and is in fresh water,
it is also insulated.

Any ideas how it may work?
Any ideas as to how I could make a ground or counerpoise?

Gary
Here are the approximate conditions. Horizontal wire at 85 feet cut in middle with 450 ohm stub 90 degrees long at 7.025 MHz. Vertex at 50 feet split source. Ground 1 medium. I have the data at home on my other computer but you can run it yourself.

I had a commerical version of the radio works superloop 80 a few years back. I had one end at 80 ft the other about 60 and feedpoint was maybe 35 ft above the ground (It was strung across a small valley). That was in Alabama and it worked pretty good. I've been thinking of building one. How do you use a mfj analyzer to figure your stub length? I can borrow one from a friend as I only have hf only without a freq counter. I also thought about making a 1/2 sized one for 40 and 20 meters. congrats on the sucess,

Here is what the instruction manual says

"Resonant frequency of any impedance stub can be measured. Select the first (or opening) measurement mode in teh MAIN menu.

"Connect the stub under test toi the "ANTENNA" connector of the MFJ-259B.

Note: The line must be open circuited at the far end for odd multiples of 1/4 wave stubs (i.e. 1/4, 3/4 1-1/4, etc) and short circuited for all half wave stub multiples (like 1/2, 1, 1-1/2, etc).:

"If a balanced line is used, operate the MFJ-259B only from internal batteries. Keep the MFJ-259B a few feet away from other conductors or earth, and do not attach any wires (other than the feedline) to the unit. Use the ANTENNA connector's shield for one lead and its center pin for the other. Two balanced lines must be suspended in a fairly straight line a few feet away from metallic objects or ground.

"When tuning critical stubs, gradually trim the stub to frequency. Adjust the feedline or stub using the following method:

"1. Determine the desired frequency and theoretical length of the feedline or stub.
2. Cut the stub 20 percent longer that calculated, and . . .leave the far end open for stubs that are 1/4 wave or odd multiples of 1/4 wl long.
3. Measure the frequency of the lowest resistance and reactance, or lowest impedance. For fine tuning look only at the "X=?" display. Adjust the "X" frequency for X=0, or as close to X=0 as possible. The frequency should be about 20% below the desired frequency if everything worked out as planned during the length calculation.
4 Divide the measure lowest "X" frequency by the desired frequency.
5 Multiply the result by the length of the feedline or stub to find the required frequency."

Good luck.

Mind you all I did, however, was to cut it a bit long and then begin trimming it a bit at a time until it was at the desired frequency.

Well, yes and no. In a typical 2 vertical array, you can steer in either
of 3 patterns on on the primary frequency. Cardiod for one endfire,
Cardiod for the opposite, and a figure 8 broadside with 1/4 W spacing.
You change the coaxial feed length to change this. You can research
this. Now at twice the frequency you will wind up with a broadside gain
or a clover leaf pattern. Can't remember how much, but both are useful
to working DX. Some software experimenting will let you discover some
tricks.

The way around the groundplane problem I used was, before we laid in the sod for a lawn, we put in rebar mesh under the whole yard. It calculated out to the equivalent of 100 radials on 80 meters. Was a little short on the sides, but was just fine on the corners. I brazed all the seams together. Worked very well for me. I know it was good as the antenna 'Q' was very high. I used butternut verticals for the radiators. I did not see any interaction between the two antenna, but sure did see a difference when working stations and flipping the switch between the different phasing harnesses. BTW, I used old fashion open frame relays mounted in a steel enclosure and used some 75 ohm aluminum jacketed cable TV coax. Was very efficient. If I had the room here, I would be very tempted to do that again. I have plenty of room horizontally, but there are lots of little trees scattered throughout the field that the land owner would be upset if I removed them. So I am "stuck" with full sized dipoles on 160 meters through 30 meters. Oh well... ;-)

Of course it didn't come from Bill Cosby.

And the same list was circulating before, attributed to someone other than Dr. Cosby.

Dig a big hole, put a tower in it and fill with concrete for a base. Now erect 500' of tower on this base. Use a crane and mount a BIG obnoxious antenna, no make that stacked arrays... OK so that won't work.

There is a really good book available through Amazon called "stealth antenna for the radio amateur" Has a lot of really cool ideas.

Sorry about the dig at the beginning... Just had to <G>

I'm going to assume you want clandestine stuff. Here are some options

1. Attic Antenna. I have a Alpha Delta DX-CC in my attic. The antenna is 80 foot long but I have it in a 70 foot area with about 5 foot on each end drooping. You could also lay this on the roof but the coils may be visible depending on you roof. Depending on your trees you could also hang it between a couple of trees but that would probably be too visible.

2. Ladder line feed random length doublet (ideal would be 135' though) with a trans match (Antenna tuner). Can be in the attic or on your roof. You can do this pretty clandestine on the roof if you use black 18 ga wire the only thing that will be at all visible is the ladder line. You can even lay it across the roof to form an inverted V. You can also bend the ends around to make a lazy Z if you need to in order to make it fit. By FCC regulation you can put a TV antenna on your roof that does not exceed 11' above the roof and the CCR can't do a thing unless they provide you free cable service. You can make your dipole the guy wires for the TV antenna as a inverted V.

3. A Flag pole antenna. You can even hide a conventional vertical inside a ray dome to make it look like a flag pole. But a piece of pipe with a SGC tuner at the base would work also.

4. A regular vertical where you lay it over when not in use.

5. A screwdriver antenna set up in the back yard with some ground wires laid along the ground. You could also do this in the attic or depending on your roof on the roof.

6. A Hamstick dipole. There is a set of plans on the internet for putting 3 bands on a electric box. You can raise it as needed or even put it in the attic.

7. A loop around the house under the eves of the roof.

Clandestine Antennas are fun, use some imagination and you can have a reasonable working setup.

5834. 6/2 meter antenna

Yahoo group: ham-antennas (2008)
Date: 2008-09-11 03:52:55 UTC
From: SweetbritchesZme@aol.com
Topic: 5834 Message: 5834

I am trying to make an antenna for 2 and 6 meters for my rooftop on my home.

What I thought of first was to homebrew a rod 57 inches long with radials to match to use for both six meters FM and two meters FM just by feeding the coax to the rig in use. Would this work?

Next I figures i might be able to put up 2 antennas with a common feedpoint one rod 19 inches long and the other rod 54 inches long would this work or do I need 2 antennas fed with certain lengths of coax to present an open to the unused antenna?

I already have a 70 inch rod with matching radials used for my scanner up on my roof fed with 100 feet of RG 213 so I am just trying to modify my present antenna system for ham radio. Maybe I just need to put up 2 more runs of coax to a 3db gain 2 meter and a 54 inch 6 meter antenna but I really dont know which way to go
I hope this is enough info Many Thanks donna

From: Mark Saunders, KJ7BS
Topic: 5835 Message: 5835

I've heard and read so many good things about the EFHWA that I had to play with one.

I have been testing my EFHWA for 40m in the inverted vee configuration with the apex at 30 feet. I like it. Compared to my vertical, it hears about 2 S-units better. On transmit AZ to IL a "solid 599" and AZ to PA a 579. I will be experimenting with the inverted L and sloper configurations in the coming weeks. Not time this weekend for antenna testing due the ARRL Southwestern Division Conference in Mesa, AZ (about an hour drive my Glendale). I'll be going afield with my son's high school Air Force JROTC corps Field Training Exercise (FTX). Sloper and inverted L testing then from Prescott, AZ.

What about doing like some of the commercial HF antenna do and use
traps? Maybe 19", a trap and finishing off with the top section to give
you 6 meters? The ground plane spokes can be interleaved 1/4 wave
elements, or treated like the vertical element, also with traps. Then
you would have your single feed antenna.

Another thing to remember -- a 5/8 wave 2-meter base-loaded antenna
works fairly well on 6 meters with no mods.

Jerry

Regular coax , short RG-8X run with 5 turn choke just under feed point.
After that 213 to shack. It is a fiberglass crappie pole from Bass Pro shop
with the thin top section removed. The top plate of polycarbonate has a ¼
hole in the center with a nylon bolt through the poly into a wooden 6☐
long wooden dowel with epoxy into the fishing rod. Two wires are 14ga copper
weld , the rest are 20ga copper. A ring of copper weld with the 8 wires
soldered to it on top and bottom. 12 radials spread to give a 50 ohm load.
Feed point will be 21 ft off the ground with a small tiltup. Tested at 6 ft
in driveway.

Rich

From: vk2pws
Topic: 5842 Message: 5842

Hi All,
All I have heard and read about Hy-Gain being so slow responding to emails and delivering orders etc, is there another method or place where I can obtain the TH3JRS Plastics Kit so that I can rebuild the beam? So far it seems (here in VK) nobody stocks this stuff, they say order from Hy-Gain or we will order it for you but it will take time, so any suggestions would be helpful. I hope I dont have to end up buying a new antenna!

Correct , when I first made it I used the standard formula for length and had to keep trimming it until I brought the SWR into range. Radials as std length.
One quick note, on first build I used old CD's as the inter spacers, they did not hold up in the weather so I cut up a sheet of acrylic for window repair and used 6mm polycarbonate for the end plates that take the tension load when the wind blows.

I wanted to run something by everyone for advise. I have a Yaesu FT-101 and MFJ Versa Tuner II that I am trying to get a decent antenna strung up on. die to space and yard layout it's probably going to have to be an end fed of some kind. Here's where I'm at:

until yesterday I had about 40' of 12 gauge insulated stranded run from about 40' high in a tree back to the eve of the house around 12' high. there it was soldered to the center conductor of RG213 coax that goes through the wall into the the shack in the basement. terminated in a PL-259. I could never get the SWR below about 8:1. Been reading up on long/random wires and inverted L's. decided to trim it down some to see if I could tune it. I cut it down to roughly 33' on the horizontal so I can use it on 10,20 and 40 meters. Spliced a ground wire into the shielding outside the house before it enters the wall and bound it to the chain link fence rail with a hose clamp. Checked SWR and no change. thought maybe my feedline was too long or too close to one of the "magic" lengths that it shouldn't be. So I cut about 3' off it, including the connector. Stripped off the dielectric and shielding and connected the center conductor to the "wire" post on the Tuner, according to the manual. Immediately the SWR dropped to about 1.6, and I couldn't really get it too tune up any better w/out further trimming. Didn't matter because the bands are dead anyway and it was cloudy/raining at my QTH so I couldn't do anything anyway.

Here's my concern. Another HAM at work thinks there is going to be a lot of RF in the shack due to just using the center conductor at the tuner. He thinks there needs to be some kind of radials somewhere or the PL-259 replaced so the feedline is shielded with the coax back to the tuner. I've read up on L's and long wires in the ARRL Antenna handbook and various sources on the web and can't find anything that proves either of us right or wrong. I'm thinking that since the braid IS grounded to the fence rail that the shielding effects should apply to the entire length of the feedline. He thinks that it only covers from the point the ground wire is connected to the feed point with the horizontal. Can anyone maybe clear this up one way or another? Sorry this is kind of long. I'm still a fairly new HAM and trying to sort out all the details. Thanks.

Mas
K0MAS

5845. FW: [ham-antennas] 20M Vert

From: Richard Schmuke
Topic: 5845 Message: 5845

When I posted my note the first time there was a problem with the link to the drawing. Now it should be OK.

http://www.flickr.com/photos/kd0zz/2849656028/

I just completed my 20M Vertical. It is a cage , 8 wire. It turned out to be only 13' 5" tall. I made it with PSK31 in mind. It is very wideband.

SWR is as follows 14.0 to 14.26 1.2:1 , 14.26 to 14.47 1.3:1

Regular coax , short RG-8X run with 5 turn choke just under feed point.
After that 213 to shack. It is a fiberglass crappie pole from Bass Pro shop
with the thin top section removed. The top plate of polycarbonate has a ¼
hole in the center with a nylon bolt through the poly into a wooden 6☐
long wooden dowel with epoxy into the fishing rod. Two wires are 14ga copper
weld , the rest are 20ga copper. A ring of copper weld with the 8 wires
soldered to it on top and bottom. 12 radials spread to give a 50 ohm load.
Feed point will be 21 ft off the ground using a small tilt-up. Tested at 6
ft
in driveway.

Rich , Kd0zz

Komas:

My first thought is the fence and posts are probably not that great a ground. I would be really surprised if they are less then a few hundred ohms to true ground. I know on several of my commercial sites we have numerous ground rods and cable loops in decent soil and these will be around a few ohms....a fence post concreted in and only several inches down wont compare to a 10-12 ft ground rod.....

I also have been exploring long wires and end fed designs. One option you might explore is connect your long wire to the crest of your roof and take off out into your tree. Then attach a second wire to the shield and run it back over the crest of your roof to the other end of the roof, making a "counterpoise"

Ive explored the lengths on my house and a 48ft counterpoise and a 113 ft long wire looks possible - until the wife sees it anyway!

Ive also pondered about the feedline being ladder wire instead of coax. Might be something to look at.

Feeding any end fed design is always a issue and some books even say its NOT really very good no matter what you do. Funny how thats how most of the early antennas were!

Maybe that helps....

Jerry, Wayne,

The Youtube video was made by a maker of Bluetooth headsets and they admitted their handiwork in a TV interview. They were trying to scare people into buying bluetooth headsets. The interview was aired by most major networks. Cell phones can not do any damage, however long term/extended effect of exposure to cell phone radiation is still unproven. Medical experts suggest that young kids must not be given cell phones due to fears of damage to their developing brain. This was shown in another TV report recently.

Better yet, build a grounded-grid amplifier -- IF you can find a source
for the tubes!

All of the above counts... LOL... Hi Earl...

On extra class, I think it just might be a sign of the times again.

Many are not using soldering irons any more. Now they use propane or butane and battery powered things. But I remember my foster father soldering with this big thing he heated up with an alcohol torch. Then had to get the soldering done before it cooled to much to melt solder. He even soldered together chassis when he was building his own transmitters and receivers. You know, he only had two peices of test equipment. A wave meter or grid dip oscillator and a simpson VOM. Seems the ohm meter always had a dead battery and he would "borrow" the one out of the silver flashlight. Oh, those were the days. The smell of rosin, burning rubber insulation and ..... flesh!

5857. Q: How-to model antennas for beginners and end-fed report

Yahoo group: ham-antennas (2008)
Date: 2008-09-14 19:52:31 UTC
From: RBB
Topic: 5857 Message: 5857

Greetings group:
The 21m end fed wire I put up is working quite well on 40 and 20. I also made a twin-lead fed dipole with a total length of 10m; it too loads up from 40-10. Built an Arnie Coro 7m sloper and waiting to hang that, too. Bands are lousy, but can't complain: the end fed wire (inverted U shape), has some directivity and work into Washington State and Oregon quite well. On 30m with the qrp rig lots of fun, again, despite conditions.

I can load it up on 80, too, but here in Mexico the band is shared and there just isn't too much on Ham-wise on the CW part of the spectrum.

Now, my question: I want to learn how to use antenna model software, from scratchl a real step-by-step guide and a program suggestion. Something a person with a college education can follow, but that does not assume an engineering background. Something I can run on this Windows Xp machine or on my Ubuntu linux laptop.

thanks,
Roberto "Rob" Barnard

Well the three vertical fence posts nearest where I have it clamped on are just bare metal about 12" into the soil. No concrete. I was too lazy to do that part! ;) The fence itself also connects to about 6 other backyards of chain link fencing. There's probably a couple thousand feet worth all together.

I do like your idea about the counterpoise along the roof live. I could probably do something like that along the underside of the eve since I actually have it it tied off at the back side of the house on the corner and not the ridge line of the roof.

RE: ladder line for feeding. Yeah, I been thinking about that too, but I have a couple hundred feet of the RG213 I got for $10 from a coworker so I was trying to be cheap again.

Hopefully the weather has cleared up around here for a few days so I can do some more tinkering. We have at least 2 tornadoes blow through the area friday night!

Hello Roberto,

Glad you have had good luck with the antennas you have. As a long time user of EZNEC, I personally can recommend it. I have the PRO version for business. The manual is quite good and straight forward. It does take getting used to using everything in a 3 D format, that is X,Y, & Z. The examples are good at letting you see how things work. I might also recommend the following site for a great tutorial and many, many examples from my good SK friend Cebik. http://www.cebik.com/.

When you get started, and if you have any questions, just drop me a line. Glad to help.

5861. Re: Inverted L ??

Yahoo group: ham-antennas (2008)
Date: 2008-09-15 18:33:22 UTC
From: John
Topic: 5844 Message: 5861

Soldering iron burns! Wow, how terrible. One time I picked up a nice little iron with a pistol grip handle. For some reason with the pistol grop I would lay my forefinger along side the barrel of the "gun". Resulting in a permanent blister on my right fore finger. Also I have in my tool drawer my Grandfather's iron, a big copper head with a long shank and wood handle. Heat it up on one of those old gasoline blow torches (that was what the hook on the old torches was used for.) and there was nothing better for running a long seam in a home built chassis.

Us, old geezers have a hard life now anyway. As components got smaller our eye balls got weaker. (how can you read a color code when all the colorss look the same?) Then those disk caps with some strange code printed on them that seem to vary with the country of origin.

Then there was my home built regen with plug in coils and B+ was something like 250 volts D.C. Changing plug in coils in the dark (when I was supposed to be in bed asleep) was a real adventure.

OH for the Good Ole Days with the blue flicker of the mercury vapor rectifier tubes. The warm red glow of the other filiments and the smell of scorched skin filling the air of the shack.

Earl
That build a tube amplifier suggestion is an example of why there is so
much disrespect aimed at the old guard in radio. The idea that anyone
would be required to know antique technology to obtain a license is so
truly transparent a case of "back in the day" thinking that I don't see
were you got the unmitigated arrogance to utter it. Why don't you just
say what you really want. 25 wpm Genuine Morse code; no international
radio telegraph code allowed of course; copied from a sounder with a
Prince Albert tobacco can resonator or get out of the hobby. Get A Grip OM.

5863. stationmaster

Yahoo group: ham-antennas (2008)
Date: 2008-09-15 19:28:45 UTC
From: Glen
Topic: 5863 Message: 5863

hello,

I need some help taking apart a high band stationmaster (21' 6" long).
150-160Mhz

I have successfully removed (unsoldered) the brass top and removed the three
flathead
screws at the base, but it does not budge. I see two Allen head bolts about
6.5"
deep on the bottom of the aluminum tube inside. Have not removed them, do
not have
a tool that can reach them.

Any ideas?

Thanks,

Glen K4KV

This may rub some people the wrong way, but in my opinion the "true ground" isn't important; and anyway, ground is far overrated when it comes to RF.

Think of the chain link fence as the counterpoise; the other (formerly missing) half of the dipole. If it is an effective counterpoise, then it won't need a connection to actual ground at all; and in many cases it works better without one (since the connection to ground introduces a loss element to your antenna).

On the other hand, the fact that the chain link fence does go into actual earth, means that it may introduce that loss element, so getting the resistance down would help, as far as improving antenna efficiency is concerned. It'll work if you don't; it'll probably work better if you do.

> Here's my concern. Another HAM at work thinks there is going to be a
> lot of RF in the shack due to just using the center conductor at the
> tuner.

I think he's right.

> I'm thinking that since the braid
> IS grounded to the fence rail that the shielding effects should apply
> to the entire length of the feedline.

The problem isn't shielding. It is providing a path for the current output from your rig ... the VersaTuner. There ought to be equal but opposite currents on its output terminals, both leading in the direction of your antenna. Right now you've got something connected to only one of the terminals, so the current that wants to go out the other terminal will need to find another path to try to "complete the path." It might force RF currents into any other wire near your rig, the power wires, mic cable, etc., and all of them will radiate and could cause RF "hot spots."

I don't know if it's enough to cause "a lot of RF in the shack," but it is definitely not the way it ought to be.

It also changes your antenna a lot, so be prepared for it to markedly alter the SWR.

Andy

From: N0ATH
Topic: 5863 Message: 5865

I use those long T handle Allen wrenches - those two screws go
thru a pair of races if you will - one is an internal taper and the
other an external taper - with the screws loosened you can move
the rings up and down and that is how you adjust the SWR - I think
the lower (physically) you set them the lower the freq it resonates.
It has been a long time since I worked on one of them - but with
them loose it should slide out of the tube - be careful not to bend
the lower tube inward as it will be hard to get apart if you do - Mine
was thrown from the top of a 400 foot tower and I had to cut off a
couple of inches that were bent and it was border line on freq after
that - Dave / N?ATH 73 & gud luk

Geez Tom, chill out! It was all meant as a slightly sarcastic joke,
OK? Having you attack me like this is certainly what I expect from some
amateur radio op who should know the Amateur's Code -- or has that
disappeared, too?

7 3 & get a grip for both of us, OK?

Chill out guys , I see some good points in knowing about an amp , building a J-Pole and other things beyond ordering from a catalog. Everyone cannot be a big enough nut to build their own variable capacitors Ref picture at (http://www.flickr.com/photos/kd0zz/2180189909) and I have my cheap J-Pole their also. I think it is a good idea to have some amount of knowing how things work. Many today pass a test then never pick up that soldering iron , or go on to know how to solder that PL-259.

Rich , Kd0zz

5873. Re: [ham-antennas] Re: Inverted L ??

Yahoo group: ham-antennas (2008)
Date: 2008-09-15 23:56:28 UTC
From: DVC3565@aol.com
Topic: 5844 Message: 5873

Tom:
Wow! Talk about a "flame!" Don't see any malice in either Randy or Earl's posts. I do notice they have "old" Advanced class calls. Maybe that has something to do with your "comment." I don't know, AND I am not going to flame you either. But not knowing your age, how long you have been in the hobby, OR anything about you other than you had a KB3 call prior to your acquiring the W3TDH call.
I don't want, nor expect the code requirement to ever come back.
However I am ALL for reinstating the requirement of being a licensed ham for 5 years BEFORE you can even test for extra.
YOU act like a fairly new ham that got his extra without paying his hobby dues, OR his practical factors. Could be wrong, and I might be. But 29 years in Law Enforcement have taught me how to profile and categorize people. If I am wrong, I KNOW I will hear back from you. IF I am RIGHT, I won't hear from you.
As always: A LID is a LID! Don't take it so personal. I didn't see anything in their comments that warranted such an ignorant, personal attack on either one of them. THAT'S one of the main problems with the hobby today.
Grow up, send me an E-mail, and lets discuss making a POSITIVE for our hobby. Instead of being another always "negative" person. I am glad for you that you got your THEORY part of the extra license. But you need a lot of work on the "practical" part. An becoming an ambassador for the hobby. Reread the Amateur code. NOT Morse code.
Just the facts! No personal attack meant or intended. Hope to work you on the air sometime Tom.

73,

Dave-KJ4PF

Thanks Troy but not much is needed , note the extra holes on the plates. You bolt the parts together and trim the outside with a file. It is made with threaded rod and store bought spacers. I enjoy making things. Check out the rack for my radios and the handy carry case for the FT-2800 , all made from plastic shelf scrap from the dumpster behind a strip mall. It is bolted together with 6-32 screws , handles for the FT-2800 tote cost the most , a buck each at the local surplus store.

Well I will try , I make things per □SWAG□*** and then adjust as required .

The vertical and radials should be about 19 ¼ inches , they are made from welding rod , go to your local shop and see if you can buy a couple of 3/32 or 1/16 heliarc rod in 17-7 or 17-4. They are SS , 17-7 has a good spring to it , 17-4 almost as good, without heat treating. They may have 321 , 316 303/304 SS welding rod but they will not spring back straight like the 17-7. They come 36□ in length. If you can□t find them go to your local hobby shop and get spring wire or drill rod. Also if you look at the bottom you will see a short piece of brass tubing that supports the SS as it joins the SO-239 ,it got that at the hobby shop. I would not advise you trying to dill the lower section and installing a thinner top part like I did unless you have good drill bits and a steady hand. The SS rod is a little hard to drill down the center unless you are used to it. I have also made a couple of them out of 14 copperweld , not as pretty but it worked.

The radials were bent to get the set up at 50ohms and a good SWR (about 45 degree)

SWAG is □scientific wild ass guess□

Rich,

That's where I saw it. I had seen it somewhere else, but seeing yours reminded me that I would like the plans.

I also looked at the J-pole.

Thanks and if possible, the plans for the SO-239.

I have a lot of Ham friends. Some build their own equipment, some
struggle to just put up an antenna. I appreciate even the ones that
struggle to open the box the radio comes in. But, those are the guys
that are willing to go out, in the freezing, pouring blowing rain, get
soaked to the bone, suffer frost-bite to do a search and rescue mission,
and don't even hesitate at 3 in the morning. These are the guys that
will make sure my kids are all right after the flood, tornado or forest
fire. I'll be there for them to fix their stuff because they are there
when I need them.

How about you?

Boy I don't know what circles you run in but "disrespect for the oldtimers" is not common in the circles I have run in for the last 50 years. There are many of us who are very interested in hands on building. Many have led the way in developiong new techniques for use of old gear. My 4-1000A is an exmaple. When I converted it to AB1 with grid drive I installed a homebrew dynamic biasing network using a drain follower. Many of my old timer friends even have such things as PhDs in antenna design and fields and still hang on the some venerable old equipment. The reality is that it is these old timers who have led the way into the modern era with many of them developing the digital based systems we all have come to love and use. Next week one of those old timers (a retired professor of electrical engineering) will testify for me in a PRD-1 hearing on the communication limitations of low height regulations.

So if anything the old timers need to be honored with the respect they deserve, which is enormous.

If you're thinking of end-feeding a half/wave wire, the impedance will be VERY high -- but I suspect it will work if you can find a way to match it to your feed line. A much easier way to do this is a quarter-wave length of wire -- you might not even need a tuner with that.

Hey Alan, include your callsign in your emails so we can watch for you on the air!

Andy, thanks for not launching into a tirade about knowing how to use a soldering iron or not and giving some input on my antenna situation. BTW: I have 3 and burnt myself numerous times over the years working on guitars, amps and effect pedals. *ahem*

back on topic of my question:

I'll add that the versa tuner is connected from it's ground lug to the ground lug on the FT-101 which has a 3-prong AC cable as well. This has always been this way. If this is not sufficient grounding I'm also welcome to advice there.

In regards to the SWR changes. Well yeah, as I said since connecting the braid to the fence line it went from the 8-9, or higher depending on frequency, range to a very usable 1.5-2 across the 10 meter band, which I could probably get even better with some more trimming on the antenna itself and the feedline.

>
> The problem isn't shielding. It is providing a path for the current output

The antenna you refer to is commonly known as a "Zepp".

See: http://www.qsl.net/ta1dx/amator/practical_dipole_antenna.htm for construction details.

It's a great antenna.

> heavy coax for the run into the reciever just a thought

If you're thinking of end-feeding a half/wave wire, the impedance will
be VERY high -- but I suspect it will work if you can find a way to
match it to your feed line. A much easier way to do this is a
quarter-wave length of wire -- you might not even need a tuner with that.

Hey Alan, include your callsign in your emails so we can watch for you
on the air!

Cool, Alan!

The information most of us give here is aimed at transmitting antennas
-- but receiving antennas benefit from the same things.

But if you're only receiving, you can put up almost anything and
receive SOMETHING. With the half-wave end-fed, just go ahead and
connect it and you will sure be surprised at what you hear.

Dave
Your right I'm afraid. I was rude, nasty, and my post was not in keeping with the attitude most took towards each other when I was first licensed. It seems to me that there is a mean streak in public discourse today and here I've gone and contributed to that meanness. So I apologize to every one on the list that I burdened with my ranting. I will make a commitment here and now to avoid making the bad worse in the future.

I was licensed as a novice back in 1975 or so. My call was WN6JCY until the FCC changed it to WA6JCY. I never did now why they did that. I built my first transmitter and a VFO to tune it. My first receiver was a lovingly used Hammarlund HQ-180-AC. I was it's third owner. The antenna was the copper flashing around the parapet of the church that I was the resident caretaker for because the elders would have been most put out by my putting up a wire antenna. That flashing worked amazingly well. I worked stations from Oregon to Florida. I suppose I could do those things again if there was a good reason but it would take me a lot of study to relearn circuits and techniques for which I would have no real use today. I do have fond memories of when you could warm your hands over the grill on top of your equipment and read the manual by the glow of it's tubes but I have no wish to go back to that equipment or to the techniques that were the state of the art at that time.

I got back into radio, a little over a year ago, to try to help my community prepare for emergencies. When I was first licensed almost every Ham I knew pitched in on that sort of thing but now many cannot be bothered. Since I don't believe in conscription I wouldn't want anyone to do what they have no interest in but why do some feel they need to attack others for having that as a focus of their radio lives. Why is someone destroying ham radio if they use digital techniques to get messages through. Why are Winlink users attacked as rich yacht owners for using a circuit that does not have a live control operator at both ends? If anyone knows were my yacht is I'll pay you a pretty good finders fee for letting me know. I will use any lawful technique that gets the traffic through. If it's not lawful to use automatic stations to handle traffic then why did the FCC reject the proposed rule that attempted to forbid it. And while I'm asking questions if a terminated folded dipole is such a joke, as some here have alleged, why are there so many of them in use world wide. Some folks here talk like giving up gain in order to obtain ease of use under adverse conditions is some form of sacrilege.

I'm an unrepentant EMCOMM trainee who expects to keep training until the day he dies. I'm just trying to learn the techniques that will be useful to my community if we ever get hit by anything as bad as Katrina. It's hard for me to see when I'm wrong at times just like anyone else. But my reply to your post was rude and boorish and I'm rotten sorry I typed it. It wasn't really about what you said. Your post was just the trip wire for a lot of frustration. I had just gotten broadsided by someone on another list for just mentioning the use of Winlink for EMCOMM. That certainly does not excuse my dumping on you so all I can say is I apologize. I regret my outburst very much.

From: Randy McKenzie
Topic: 5844 Message: 5894

My call belonged to one of my closest ham friends, Frank, who shared HOURS of QSO's with me on the air over many years. I always admired his call and after be became a SK, I felt it a honor to take his call. I didnt think about his call until years after his death and actually found it available when I upgraded.

I meant no malice toward anyone, I was having some fun.

I work everyday in communications, mostly public safety, and honestly enjoy building everything I can, as a way of learning, exploration and just a big kid's curiosity. Antennas are one of the places I try things and explore more than any. I have home brew antennas on HF mobile and make good solid contacts, and always learning as I go. I have no problem with hams that buy everything off the shelf, the main thing is for them to enjoy the hobby! Its just my enjoyment to experiment and explore, to me thats what keeps ham radio interesting!

Im the guy thats rarely on the local machines, but always available to help tune duplexors, replace antennas or even build a repeater. Im also the guy that wants to talk about ANYTHING other than public safety when Im those repeaters too!

Not sure why the feathers got ruffled about these posts....

From: Randy McKenzie
Topic: 5844 Message: 5896

One note about chain link fencing, I found years ago at a broadcast station, those links are not electrically connected, they are mechanically linked. I had a joint corroded once and it demod'ed the AM station when it got wet!

You COULD run a wire along the top of this fence.....that would give you something to use as a counterpoise.....

Ive been reading about Zepp feeds and end feeding long wires. Im sure there are alot of info on the web, might be worth searching to see what would fit on the roof. Hiding a wire on a ridge or even under eve trim would be possible.

My thought with ladder line was using my MFJ tuner with its built in balun, a "modified G5RV". 213 could be terminated into a balun and then to your antenna.....

Good luck!

Once you get it apart, check all the solder joints VERY close. I recall one that had a couple of cracked solder joints, causing intermittant SWR issues when it was top mounted and suffered thru some pretty rough winds and ice. It flexed it over enough to stress crack the joints. After we repaired it we side mounted and gave it some support.

Aw shucks, Tom -- we all have a rough time somewhere, sometime. I've done the same thing from time to time and always regretted it later.

And although I have read some negative things about Winlink, I really don't know anything about it -- the real thing I worry about today is ALE -- I worry about it dropping someone right into the middle of my ongoing QSO.

At any rate, Tom, don't worry about it, it's all in the past and forgotten.

Now about that amp --grounded grid, or driven grid... <G>

Very close to a J-Pole. :) Make one out of 300ohm TV cable with a notch at the appropriate spot on the matching stub side and feed directly with 50ohm coax.

> welcome to advice there.

I'm trying to steer you in the direction of thinking about where the
current goes; not just thinking about whether or not things are grounded.

Power gets to the antenna by having some voltage and some current from the
tuner to the antenna. An equal but opposite current is trying to go out the
ground lug on the tuner. Right now you have it going to the ground lug on
the FT-101 and from there to AC ground. This is now your antenna too.
Well, half of it.

The RF current that takes this route, will radiate. It also causes the
"ground" at the rig to be different from the ground rod where AC power
enters your house. While it's impossible (or nearly so) to make those two
ground electrically the same, you may be causing it to be more different
than it needs to be, by forcing RF current into that ground path.

Where you want that current to go, is out the shield of the coax and toward
the vicinity of your antenna.

That's why I think you don't want to leave the shield of the coax
disconnected at the VersaTuner.

On the other hand ... if it works, if the SWR is reasonable and your signal
gets out, and you don't get nasty side-effects (like RF burns), then why
complain.

Andy

Hi Alan,

For receive purposes, just about anything stuck into the receiver port will hear something. Now whether it will be efficient, that depends. If the wire is an odd multiple of a 1/4 wavelength, it will do OK, but even harmonics will suffer. There is the reason. 1/4 wavelengths are close to 50 ohms. Actually will be somewhere between 35 and 75 ohms, depending on the height above ground. Even harmonics like 1/2 wavelength will be very high impedance, on the order of 5000 ohms. The 100:1 SWR will make the coax act more like a long attenuator than a transmission line. This of coarse makes the received signals very weak. It could mean you won't hear some stations.

There are many antenna designs that attempt to overcome this problem, including an end fed Zepp, an OCF (off center fed) antenna, and the loaded sloper. Another option would be to place in line at the end of the coax a box called an antenna tuner or matcher. Then the wire can almost become frequency independent.

All of the options will allow you to transmit as well, if someday you decide you want to.

5902. Hardline coax

Yahoo group: ham-antennas (2008)
Date: 2008-09-16 20:44:22 UTC
From: Dave
Topic: 5902 Message: 5902

I picked up a bunch of 7/8" hardline today for free, but some of it has dents or kinks in the outside conductor. I think the stuff is still useable but does anyone know how dramatically these dents might effect the overall performance of the coax itself?

Also, if I broke the line at the point of a kink and inserted a 1:1 connector would there be a significant loss in performance?

Thanks in aadvance.

It all depends on what frequency you are going to
use.. Two meter and even 70 cm the dents should
not bother too much...
As far as a splice... Do you have Any idea what that
will cost? It would almost be cheeper to just buy some
good RG 8. You could Make you own splice but it
too would make an impedance bump. One inch copper
pipe fittings make a good outer shield.

Thanks Mike. Good suggestion. I found this at the Michigasn State University salvage yard. They were getting ready to throw the stuff away, and ther's easily 2 or 3 100' rolls in the lot. I stuffed as much as I could in the back of my Trailblazer and will go back for the rest tomorrow, if it's still there.

Thanks again.

Dave

First of all welcome to ham radio, Mas.

I got my novice license way back in '66 and got a lot of bum information from "experienced " hams and understand how frustrating getting on the air can be.

You had a lot of responses that unfortunately took all kinds of tangents and some offered just plain bum information.

Your dilemma can be easily solved for the moment, but, don't expect the same results you could get from a complete antenna aloft like a dipole or a loop or whatever.

What you are trying to do is make a less than full-size antenna work by correcting the mismatch of the antenna to the radio by using an antenna tuner....

You can do that, but, let's clean things up a bit.

First of all, understand that "GROUND" is NOT a part of your antenna...We only rely on grounding for lightning protection and a way to dissipate stray RF...that's it!

When you read about 1/4 wave radials buried every 3 degrees around a broadcast tower...those are part of the antenna...THEY ARE NOT PART OF THE GROUND!

With that said, you can use a random wire shorter than some resonant length wire at some frequency...but, you lose efficiency very

quickly if you don't make up that lost antenna length with some kind of "counterpoise"...(a fancy word for radial or the missing part of an antenna)

Just don't expect "GROUND" to replace antenna length...
If we could do that, we'd just stick our outputs into the ground and go at it!

You can use that 40' "random wire" of yours by just removing any coax between your antenna wire and your tuner and just run the antenna wire right out of the SO239 output jack or connect it to the unbalanced wire terminal...

Make sure you properly ground your station by stabbing a couple of 8' ground rods a few feet apart, ouside your shack, and tie all your equipment to it...

Tie your grounds together with #8 wire and mechanical clamps to a single point in your ham shack...

Oh yes, don't forget to run some #8 to your "service" ground...
Yep, they're ALL supposed to be tied together!...

I also tie my outlet grounds in my hamshack to my hamshack grounds to "short out and equalize" the high frequency component of lightning and other transients.

Forget about the fence as part of your ground...But
that's "Experimentation"...if you want to get on the air, I'd say forego the fence as part of your antenna for the moment.

Hope I didn't spin your head too hard!

Mike, WA5PSE

5910. Introduction---and invitation to my TV Antenna forum

From: Robert Williams
Topic: 5910 Message: 5910

Just wanted to introduce myself. I've been a SWL for over three decades, with a dormant Technician class license for over 14 years. Just never had the cash to get set up with the gear I needed. Maybe providence will smile on me soon. I'd like to know what would be a good beginner/first time antenna for me to start out with. I live up here in the Oregon hills with plenty of room if needed.

Also, I'd like to invite anyone interested to come over and join my TV Antenna forum. It's a place to discuss VHF/UHF TV antennas (not satellite dishes) and any related hardware. The intent is that amateurs and experts alike can come together to discuss TV antenna problems, and discover practical solutions. With the US conversion to digital TV broadcasts (DTV) on February 17, 2009, I expect a huge resurgence of interest in this all but forgotten technology. Here's the link:

There is always added loss from adding a connector, or in the case of a splice, there are 2 connectors, possibly 3. The amount of loss depends on the quality of the connector and the quality of the installation of those joints. I would think that the losses would be very much outwayed by the efficiency of the feed line. 7/8" will probably gain you 1/2 the losses of RG-8 as a guess. The cost you got that stuff is pretty good too.

As far as the dents are concerned, this will depend on how deep the dents are, and the frequency. If these are superficial dents, then I wouldn't worry. If they are really deep, then you could have a problem. How about you terminate the stuff with a good dummy load and operate the transmitter into it? Then before you install it you will know what the feed line can handle.

If this is the typical aluminum stuff used for CATV/Cable TV, then it is 75 ohms. So you will need to adjust to using it and what your SWR/Watt meter will read.

If I had the opportunity to get some again, I would use it. I used some for my phasing harness for my dual butternut set-up on 75/40 a number of years ago. It was really good stuff. Also, sometime in the late 80's, there was an article in QST about making home made connectors for that stuff using copper plumbing parts.

This clears up quite a bit for me. I'm guessing the way I have it now the fence is actually acting as the counterpoise, but it's not grounded properly for protection. I do have enough wire to re-run it with no coax to the 'wire' post on the tuner, I may try that this weekend. My shack is in the basement(finished)and there is an old service ground rod outside the window I could use to tie everything too. Thanks.

Robert

Go ahead and get yourself on the air... receiving signals is a lot of fun, but sending is even moreso. With a weeks study you can probably even get your General.

As far as first time antennas... go with wire. A dipole for any frequencies you are interested in is easy as can be to make (each leg is 468/freq). If you want to get more sophisticated a half square antenna will give you about 6 dB of gain (1/4 wave length hanging down on one side, 1/2 wave length horizontal leading to another 1/4 WL hanging down. Feed at an upper corner.

For 20 meters then you need about a 33 foot horizontal span in both cases. The higher the better for a dipole, the lower the better for a 1/2 square.

For a general purpose antenna ressonant on all the ham bands go 40 feet on one side, 90 feet on the other and feed through a 4:1 or 6:1 balun (these can be made or bought cheaply).

If you want to go commercial google the Buckmaster antenna.

From: yash@aol.com
Topic: 5914 Message: 5914

Had a t-10 log on the tower,here in south west florida. Huge antenna,had to come down with the passing of each hurricane or big storm. This got to be a bit hard for myself and the xyl...telescope and tilt tower. I finally sold the log antenna. I put up a gap Titan,had it up for a while performance was about on par of a dipole,maybe.
??? I work mostly 17 meters and 20 once in a while. Would work 10 if it were open more often ,was always my favorite band. I do a net or two on 40 have a dipole for that ,works ok. Iam looking for a new antenna for the tower. I want something that is not huge as the log was. Want to cover, 20,17,15,12 and 10. I have thought of such smaller?antennas as a Hex beam, cuschcraft ma5b,and simular small footprint beams.....any body have any suggestions. I know I can go to the reflector for each of these antennas and others,but find the members on a reflector for a pertictulat ant or product are of course very biased on their? product. I thought this being a GENERAL info? reflector on antennas ,I could get some guideance on my selection of a antenna.
?? well guy ,thanks for reading,hope someone can point me in a? good direction.
thanks

5916. OT - 75 Ohm Coax

Yahoo group: ham-antennas (2008)
Date: 2008-09-17 12:46:03 UTC
From: Allan Kissack
Topic: 5916 Message: 5916

Slightly off topic....
I want to re-wire my TV leads with better standard 75 ohm cable. However all teh UK sources I can find have only upto 60% braid coverage (albeit with foil as well).

Is there a source of 80%+ braid covered 75 cable available?
If not is 60% with foil any good by comparison?
Can RG58A/U be used as an alternative or will the impedance mismatch negate any gain

thanks

Actually 468/Freq gives you a total dipole length. Use 234/Freq to get
each leg.

Hi Dale, I built the Broadband HEX and it works great. I'd been using a TGM 2 el hybrid quad for about 7 years and its done good for its size (16 lbs), its really narrowbanded. The hex beats it and was not that hard to build (harder to find all the parts). Thats my recommendations. 73, Alan

I would recommend one of the SteppIR antennas...either the two or three element yagi. You get all of your desired bands plus 6 meters. They seem to survive high wind and a salty environment better than aluminum antennas. Have a look at their FAQ page on their website
http://www.steppir.com/FAQ.html
The ratings are very impressive and there are quite a few being used in Florida. The four element antenna is big, heavy and would not be any easier to handle than your T-10. The two and three element antennas, on the other hand, should be a lot easier to manage and still provide reasonable gain, F/B, and an excellent match across the entire range of coverage. Since 1957, I've used most every kind of rotary antenna...some home built and others commercially made. I've had 2 and 3 element cubical quads and 3 and 4 element monoband and multiband yagis made by Hornet, Wilson, HyGain, Telrex, Force 12 and homebrew. The SteppIR is, by far, the best that I've ever used. Not that it has any more gain than other 4 element yagis that I have owned, but its ability to tune to any spot in the band (automatically, if you have the interface), go 180 degrees almost instantly and also work on all the SWBC bands in between 20 and 6 meters make it better than all the others I've used. My opinion...YMMV.

A great resource for you is www.k0bg.com . Alan's site has some great information. However, the one thing you will take away is at HF the key is bonding the vehicle together event if it is a unibody. Read his site and heed the advice on bonding.

As for antennas, I don't believe you can find a more efficent antenna than those made by Hi-Q and more recently Scorpion antennas. With these antennas it's all about coil Q. There are many other mobile antennas available each with their good and bad points.

Do a little research of which you've already begun by asking here.

5925. Butternut Vertical

Yahoo group: ham-antennas (2008)
Date: 2008-09-17 16:40:41 UTC
From: w8okn@charter.net
Topic: 5914 Message: 5925

Need some help...

I just was given a Butternut vertical. A long time family ham friend just passed away. I need help identifying it and piecing it back together. One of the coils is broken and so forth.

If I can get help identifying, I can download a manual and go from there.

Is there anyone on the list that can tell me which I have, if I send them digital photos?

Thanks,

From the desk of W8OKN, northern Michigan

All the Butternut antennas (except the "2" series) are the same. Download the manual for the HF9V and only use the sections of the manual for the parts you have. The only "yah-but" is that there were 2 different "6" models. One early and one late. Not a lot of differences but some.

Clint - W5CPT - HF7V (was a "6" and I added a band)

Hi Dale,
No question about it, the 4 element SteppIR is big, heavy and unwieldy.
It was a bear to mount on my tilt over tower. However, the 2 element
yagi isn't nearly so big and heavy. It weighs only about 30 pounds and
its boom length is less than 5 ft. The control wires can be
disconnected by installing a plug and socket and the feedline is easily
disconnected as it is a PL-259/SO-239.
The hex beams may be the answer, but I've not had any experience with them.
Good luck, OM.

Allan,

Try WF-165. It☐s same style as RG213 but 75 ohm.

Nevada stock it.

See http://www.nevadaradio.co.uk/acatalog/cable-wf1651.html

I☐m doing exactly the same as you, replacing my cheap crappy stuff with
WF-165 to cut down on home-made interference.

Cheers,

Callum McCormick

To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] OT - 75 Ohm Coax

Slightly off topic....
I want to re-wire my TV leads with better standard 75 ohm cable. However all
teh UK sources I can find have only upto 60% braid coverage (albeit with
foil as well).

Is there a source of 80%+ braid covered 75 cable available?
If not is 60% with foil any good by comparison?
Can RG58A/U be used as an alternative or will the impedance mismatch negate
any gain

thanks

Yes I have an early HF6V to which has been added the 6M stub, and the 30M coil making it an HF8V (which Butternut never offered). They went from an HF6V to the HF9V. Mine does 80, 40, 30, 20, 17, 15, 10 & 6 Meters. I have had it for about 15 years buying it used. I moved a lot and put it up everywhere I went. It is a little worse for wear and right now only has the 80 & 40 M coils on it. It has had as little as a ground rod under it with no radials to a full radial field of 60 66' radials. It works better of course with the full radial field, but in soggy bottom soil as I had in Texas it worked quite well with only the ground rod. If you plan to use one, plan on as many radials as you can manage as long as you can fit. Only one rule for ground mounted verticals when it comes to radials:

More and longer is better !

Don't sweat the number (as long it is over 8) or the length (as long as it is over 33'), and they don't have to be straight or perfectly spaced. Elevated radials are something else altogether. Numbers and length and layout do matter when you elevate the radials. I did it once and will never attempt it again as I lost more than I gained by elevating the antenna and radials but others have made it work. They are sort of like Quads, great if you can keep them in the air but they don't work worth a hoot laying in a pile in the yard. (but I digress).

From: frontrowe1
Topic: 5933 Message: 5933

First, thanks again for letting me post here. From the response, it seems like many of you can use these signs.

I have two different signs up on a new ebay auction.

One is an RF Caution sign with all of the details to make your RF area safe and legal.

The second sign is a No Climbing sign which gives warning that your structure should only be climbed by qualified individuals.

Both of these signs can provide validation and protection for your communications facility.

View both of the signs and details by pasting this link into your browser.

http://shop. ebay.com/ merchant/ brjecass

Don't hesitate to ask if you have any questions or need more info.
Thanks for looking.

5935. Indoor loop antennas for QRP transmitting

Yahoo group: ham-antennas (2008)
Date: 2008-09-18 12:52:09 UTC
From: geo
Topic: 5935 Message: 5935

Hi

I'm interested in seeing what exists for relatively low power (under 50 watts) indoor transmitting loop antennas to cover shortwave transmitting?

Does anyone have any suggestions?

Thanks.

Tom ,

They are in all the ARRL hand books and antenna books, it is a loop of coax shaped like a trombone and help match the antenna to the coax.

Can't you direct feed a j-pole to 50ohm coax? Why a 4:1 BALUN?

5938. "trombone balun" = RF choke

Yahoo group: ham-antennas (2008)
Date: 2008-09-18 14:19:50 UTC
From: vaclav sal
Topic: 5886 Message: 5938

This "trombone balun" is not a matching device. It is a RF choke blocking current on the OUTSIDE of the coaxial feedline. This current will radiate unvanted RF and its radiation is dependent on the length of the feedline.
For detailed explanation see Maxwell's W2DU Reflections II.

The dual band J-pole made by Arrow is direct fed at the base (end fed) and works fine.....

i put it at the top of my MFJ-1798 for another added band (still looking to add 60 meters !!!)

You can and do direct feed a J-Pole with a 50 ohm coax , at the 50 ohm point not at the end. You were taking about end feeding ½ a dipole, I think. Are we talking about an end fed Zepp , dipole or J-pole ??

I was wrong to use the word ☐match☐ with the trombone.

The Arrow is end fed as you say , it is a ¼ wave vertical on 2m with the ¾ wave element next to it. The difference with most J-poles is the construction, they have all parts connected without an insulator and the tapped at the 50 ohm point. The arrow is a good set up but cost too much for me as does copper. I made my j-pole from scrap plastic and a stick of ½ conduit. I have made several for our club members.

Dunno. I said something about an end fed Zepp being very similar to
a J-Pole, somebody else wrote back and said it wasn't "similar"
but "the same" and then said to feed it with a 4:1 trombone BALUN.

I spend most of my days confused, no reason this one should be any
different! HI HI

I have the AV-640 and absolutely love it. From Pennsylvania I've worked South Africa, all over Europe, Alaska, Japan...everywhere, and I've always got great reports, all done running only 100 watts. My antenna is mounted only 10 feet above ground. So, if you can get one, you'd be very happy based on my usage. Enjoy!

John ,

it is the same today as it was 30 years ago. My first SSB rig was a set of Kenwood twins , I loved them but was told by the □old guard□ on the air by more than one that I should get Collins equipment for better audio and receive. I still run Kenwood HF and VHF today.

I love to build , you keep operating so I will have something to build. It won□t work without all of us.

5949. Super J pole success

Yahoo group: ham-antennas (2008)
Date: 2008-09-18 21:02:56 UTC
From: Randy McKenzie
Topic: 5949 Message: 5949

I found some plans for a "super J pole" on the web and decided to try it out. The super J is a 1/2 wave above a normal J with phased 1/2 wave section making a colinear. The notes said a gain of 6db.

I figured the size and actually built one for 161 mhz to use with my scanner to listen to railroad (Im a big railfan too)

I constructed the lower portion from scrap 1/2 " copper pipe and the top section from a salvaged mobile whip. The 1/2 wave section was made from #14 solid wire.

I first built the lower section, tuned it to 161 with my MFJ antenna toy. It tuned 1.0/1 and then I adjusted the top section.

I also compared the super j to a 1/4 wave ground plane.

The results:

The j pole alone measured 3 db gain over the ground plane.
The super J measured 6-7 db gain over the ground plane.

Notes of interest:
The 1/2 wave tuning section works best when out to the side. If circled around the mast it lost about 2 db.

If your looking for a neat little antenna and some decent results, give the Super J a try!

Randy

Thanks for the reporting the test , I also built one but did not test it. I keep talking about a test set up it but did not get around to it. The phasing section on mine is straight out to the side and from 14ga copperweld. It is for 146Mhz. I used PCV for the lower section with copper wire on the outside the PVC, then the phase section with a SS whip on top.

The results:

The j pole alone measured 3 db gain over the ground plane.
The super J measured 6-7 db gain over the ground plane.

Notes of interest:
The 1/2 wave tuning section works best when out to the side. If circled around the mast it lost about 2 db.

If your looking for a neat little antenna and some decent results, give the Super J a try!

Subject: [ham-antennas] Super J pole success

I found some plans for a "super J pole" on the web and decided to try
it out. The super J is a 1/2 wave above a normal J with phased 1/2
wave section making a colinear. The notes said a gain of 6db.

I figured the size and actually built one for 161 mhz to use with my
scanner to listen to railroad (Im a big railfan too)

I constructed the lower portion from scrap 1/2 " copper pipe and the
top section from a salvaged mobile whip. The 1/2 wave section was
made from #14 solid wire.

I first built the lower section, tuned it to 161 with my MFJ antenna
toy. It tuned 1.0/1 and then I adjusted the top section.

I also compared the super j to a 1/4 wave ground plane.

The results:

The j pole alone measured 3 db gain over the ground plane.
The super J measured 6-7 db gain over the ground plane.

Notes of interest:
The 1/2 wave tuning section works best when out to the side. If
circled around the mast it lost about 2 db.

If your looking for a neat little antenna and some decent results,
give the Super J a try!

Oh yeh,...before someone catches my error..."Technically" and
accordng to Nat. Elec Code, you're actually supposed to use #6 for
grounds, but, I use #8 because it's so darn much easier to work with
and I personally don't see the #8 being burned up since there is so
much ground resistance...
Besides that, beyond the service entrance, the NEC doesn't really
address lightning protection for a radio station...that's pretty
much up to us!

Ken , you are right on.

this is the same link I used for my starting dimensions ,only difference
with mine is the top 36□ is 17-7 SS heliarc rod.. I tried one inside the PVC
but it throws the tune way off and I did not follow up with it inside. I did
not have my MFJ analyzer at that time, I need to retry one inside now.

Probably the most popular HF mobile antennas around, but not particularly efficient. Unless you're running high power, don't get the big resonators, the small ones are just a bit less lossy.

The masts appear to be aluminum tubing -- they bend easily, but the straighten just as easily if you don't get in too big a hurry with it.

In my experience, they work well on 10 through 20 meters, so-so on 40, and not so well on 75.

They are VERY easy to set up, and you can even mount the 2-foot mast and 3 resonators on a CB-antenna mirror mount on an 18-wheeler. In case that's important.

If you get one of the 56" masts, don't buy one with a fold-over joint. They always seem to crack at that joint.

Adapters are available that will allow you to put multiple resonators on the Hustler masts -- and they work. I used to run 5 resonators on mine -- all worked just as if they were the only resonator on the mast, with the caveat that I had to adjust tip lengths just a bit.

I uploaded some pics showing the details of the J pole I built.

Main support and tuning stub is 1/2 copper pipe. Insulator section is PVC female adaptor and a sched 40 plug. The top section is a mobile whip.

This "super J pole" uses 1/2 wave over a 1/2 wave. Measured gain is 6-7 db over a ground plane.

I installed it at my office today, mostly to listen to local railroad radio, and so far its been great! The J pole was cut for 161 mhz.

No reason the same results cant be found on 2 meters!

Allan,

Try WF-165. It's same style as RG213 but 75 ohm.

Nevada stock it.

See http://www.nevadaradio.co.uk/acatalog/cable-wf1651.html

I'm doing exactly the same as you, replacing my cheap crappy stuff with
WF-165 to cut down on home-made interference.

Cheers,

5969. How many radials are needed on the roky-sand soil to inatall multiband vertical?

Yahoo group: ham-antennas (2008)
Date: 2008-09-19 20:43:56 UTC
From: xperts88
Topic: 5969 Message: 5969

Hello I am Tim, I would like to ask anyone
how to measure the impedance, VSWR to use choke bulun out side
the lowest band radials to install manufacture's multiband verticals
with radials? and using a MFJ259B, how to avoid the body effect
to measure them? the closer, the worse data I get?
Next is how much radials do I need for every band (10-80m)on the
rocky-sand soil not burried any radials just one wood piece for a
vertical fixed.Now I put two radials for every band(total amount of
the radials are five folded for the antenna bands so 10 radials) but
even the 10m band could not be tuned and other band could not do so.
I understand somehow to need radials up to 120 but I have restiricted
space so anyone know how to spread and how many radials on the dry
soils to work propery?
I would like to much more informationso I post here.
Tim AH2E

OK.. well, there's other stuff the professionals use. Wait until tomorrow, I have some in the garage that's same size as contractor's coax but 10 times the quality.

I'll get you the type tomorrow.

From: Callum M0MCX
Topic: 5969 Message: 5971

Tim,

The bottom line is that you will get a 50 ohm match with great SWR with a pair (two) of quarter wave radials raised above the ground sloping down 30 degrees from horizontal, 180 degrees apart and about .2 wavelengths above the ground. You will be achieving roughly same performance as around 60 buried radials.

You can vary these variables a lot (but not the quarter wave dimension) and it won't make too much difference at all. Just elevate yours a couple of feet off ground as a test.

You can do this for all the bands your antenna is supposed to work and all will be fine.

(Of course, if you are heading for grounded radials, this is a different story.. You need lots as discussed, certainly 60+ but I'm not sure what will happen to impedance. I always build elevated radials).

See here for this year's winter vertical project using SG230 as a matching system. Works as a 5/8th on 20m band - just put it up last weekend. Works well on the lower HF bands.

- http://www.m0mcx.co.uk/gallery/index.php?/category/78

Good luck,

Callum McCormick

Randy ,

Very nice work on your antenna. I might try one like it. I
did a rough and cheap stacked □super j-pole□. I used ½ PVC conduit , and 14
gage copper for the vertical parts, 14ga copperweld for the phasing element
. Regular 14ga copper was not stiff enough for me at 2m. SS welding rod
for the top of the upper element. I added pictures of mine on the 2m band
in the Kd0zz folder of the group. I have not put mine up as I was waiting
until I had other antenna work to do , it will take the place of my j-pole
sitting on top of my beam. Like I said I like the looks of yours better.

Rich , KDØZZ

All:

I uploaded some pics showing the details of the J pole I built.

Main support and tuning stub is 1/2 copper pipe. Insulator section is
PVC female adaptor and a sched 40 plug. The top section is a mobile
whip.

This "super J pole" uses 1/2 wave over a 1/2 wave. Measured gain is 6-7
db over a ground plane.

I installed it at my office today, mostly to listen to local railroad
radio, and so far its been great! The J pole was cut for 161 mhz.

No reason the same results cant be found on 2 meters!

Real world measurements : DB gain over a 1/4 wave ground plane.

I measured the levels on two scales, DB and microvolts. Compared the levels on a "bare J" which was just the bottom section, and then the "super J" with the top section and phase section added.

The bare J gave about 3 db gain, and the super J about 6-7 db, again gain over a ground plane.

I built this one for the railroad band, design center at 161, and then for my tests I used the local NOAA station as a second test.

Measurements were made using a IFR1200 Service Monitor.

Personally I dont care of the dbi ratings, how can you reference something thats not really possible? Give me real world, a dipole or a ground plane!

Thanks for the nice comments Rich!

I used the copper pipe because of the success I have had with it on HF mobile antennas, plus I remodeled my Grandfathers house and the copper was coming out and PVC going in, and as a good ham, I couldnt let the pipe go to the recycle depot!

If I was to make any changes, I would use the gray PVC conduit parts instead, just because they are supposed to be more UV tolerable.

The top whip is mounted onto a 1/4" stainless bolt, making the top section very easy to build. The whip and mount was salvaged from a old business band whip. I drilled the PVC cap in the center and used a star washer under the head and a large flat washer on the top side. The #14 comes under the same nut and bolt with a large ring terminal.

The bottom section of the PVC is a 1/2" female adaptor, and the copper has a male on top. My first test was soldering the wire onto the male adaptor but then I opted to using a small ring terminal and a screw to allow it to be taken apart if needed.

I will try to draw up my plans and post them later.

Hello Tim,

Almost sounds like you live in a place I used to live, Rio Rancho, NM.
It was very sandy and rocky soil.

What I used for a ground radial system (only will work with ground
mounted antenna) is stuff called "rebar mesh". This is iron wire laid
out in a grid and comes is 50' rolls about 6' wide.

I laid mine down on the ground, side by side, 5 rolls, and basically
filled out the back yard before the sod was laid down on top of it. All
the junctions were brazed together. This made what appeared to be a
solid square of conductor, 50'X50'. It was much easier than trying to
measure out 120 radials.

I don't think there was any measurable difference from using 120ea 65'
long radials. I worked just about any station I could hear and always
got excellent reports.

The ground plane, if you will, must have been pretty good as the tuning
range on my butternut antenna was very narrow, meaning the 'Q' was good.

Would I do it again? Yup, in a heart beat if I needed to.

Probably wouldn't want to do that -- the gray PVC pipe is not "RF transparent" the way the white stuff is. Everybody I've ever talked to that has wound a coil on gray PVC has the darn thing sitting in a corner or else thrown away -- as it gets hot, the loading changes, rendering it unusable for an antenna.

No, actually I went to this stuff (gray PVC) after the white stuff fell
apart after a year. I have run 1000+ watts through these traps for
years. Maybe at UHF there's a problem. Don't know as I use other
materials for antenna for 144 MHz and up (Teflon) but I haven't seen any
problems using the gray PVC. The white disintegrates with the UV really
quickly. The gray is also available in thinner stock than I think the
white (schedule 40) if you look for conduit verses water pipe. This
makes for lighter items suspended in the air.

My 5 peso's worth.

I don☐t think the white is ☐transparent☐. I made a ☐slim jim☐ style 2m on a stick of wood molding , swr was just fine , placed it in white PVC for protection and lost it completely . Next I made a ☐slim jim☐ with 450ohm line on the outside of grey PVC and a friend is using with no problems. The grey PVC on my stacked j-pole is being used as a support for the wire , so if it is conductive a little , so what? Just rambling like Steve

Earl and the group,

I did an experiment last night that you might find interesting. I cut 2 pieces of PVC, one gray 2" diameter by 3" long. Same dimensions for a piece of white PVC pipe. I put them together in the microwave, a 1200 watter from Wal-mart several years ago but still strong. I put the microwave on medium power and let it run with both pieces in the box and rotating on the dish for 30 seconds. When the bell rang, I removed the two pieces. They were both equally warm. They both measured 138 Degrees F.

My conclusion is that they both absorb the same amount of RF energy. So, I guess on my next build I will try to find some 2" diameter Lexan plastic.

Now I wonder if I should order clear or black? ;-)

5983. Re: end fed dipole

Yahoo group: ham-antennas (2008)
Date: 2008-09-20 15:51:09 UTC
From: Paul
Topic: 5886 Message: 5983

A J-Pole is an end-fed dipole.

A Zepp is an endfed dipole.

The matching network in both cases is a shorted 1/4 wave open wire stub (balanced).

This stub is fed at the point where the impedance is equal to that of the feedline. The feed line should be either balanced line or coax and a bulun.

The easiest wasy is to use a balun which will also perform a 4:1 impedance transformation. The balun that does this is the "trombone".

See:
http://ph.groups.yahoo.com/group/ham-antennas/photos/view/7179?b=1

and:

http://ph.groups.yahoo.com/group/ham-antennas/photos/view/7179?b=2

and:

http://ph.groups.yahoo.com/group/ham-antennas/photos/view/7179?b=3

Measured gain on this co-linear antenna is 3.5 dBd or 5.6 dBi and for those who insist on using a 1/4 antenna as a reference 6.5 dBq.

If you want to extend the the life of the white PVC, you might try
painting it with latex paint which is also available in spray cans if
you look (I've just brushed it on). Latex doesn't adversely affect
the PVC as does solvent based paints and should be RF transparent.
The gray PVC is callled CPVC and is code approved for hot water
lines, and the white stuff is not.

Hi Callum I had seen your website years ago hi hi---I know
you have a great space you can choose to bury or elevate radials.
Thank you for your elevated radial as I know.
but 5 or 6band, I could not have set them as my trapped vertical
includes 80m and 50ft 33ft elevated radial in not real thing for
me. I need to intall them on 30x40 ft around land lot.
So if you or anyone has a good ideas , please let me know.

Hi Steve,
Your idea is great and it works for multiband
!
but I have 30x50ft land lot . very restricted land lot.
How cand I do that?
Tim

OK, I cant resist!!!

How was the plastic after cooking? Was it chewy? What sauces do you recommend with PVC???? VBG!!!!!

Actually, I figured the gray conduit would be better for UV, since its approved for outdoor electrical, like entrances. When I built the house I even used it on the roof vents for the septic, figuring two things, the gray was better with UV and it matched the shingles better than blazing white.

Also, I installed the J pole during a wonderful weather day, violating the ham rule about putting antennas up, but I honestly couldnt wait till it was cold, snowing and icey!

Does this mean I lose a corner off my ham ticket?

5988. Attic HF antennas options? Ideas welcome

Yahoo group: ham-antennas (2008)
Date: 2008-09-20 18:25:48 UTC
From: Randy McKenzie
Topic: 5988 Message: 5988

I have been exploring what I can install at the house without getting the XYL into war mode. So searching my options, the attic is first on the list.

The dimensions are 48 ft long, 32 ft wide, and 6 ft high (4/12 pitch) and constructed with wood trusses. Very few items in the way: one 16 inch stove pipe, 2 plumbing vent lines and one TV antenna not being used. The long dimension is almost due north and south.

What could I get in there and not create a spider web mess for access?

I tried to plan ahead and currently have 4 runs of Belden 9913 coax already there and running down to the basement near my ham desk.

A 20M dipole would fit easy, but surely I can get something more????

Experiences with attic antennas? Input appreciated!

Randy

Not all gray pvc is CPVC. CPVC Conduit is gray, but It is not rated for
pressure, but rather it is a water resistant container for conductors.
CPVC is the only one that is Power Factor rated, @1000Hz it has 0.007%.
See <http://www.harvel.com/piping-cpvc.asp?source=yahoo&adgroup=cpvc>
It is able to be buried. Schedule 20 is good for low pressure stuff like
sprinkler systems. It is also the right stuff, as far as I am concerned
for my uses, for coil forms and traps as it is lighter in weight.
Something to consider when suspending a couple of pounds of wire as a
dipole with traps.

CPVC has an upper working temperature limit of 200?F. PVC is rated for
up to 160 degrees F. CPVC is preferred over PVC in some applications
where improved fire and heat resistance are required.

(C)PVC can be aquired in different pressure ratings starting with
Schedule 20 and goes in multiples from there, IE. Schedule 40, Schedule
80 and for really high pressures of up to 7,750 PSI there is Schedule
It may be available in higher ratings, but not what I would be looking
for anyway.

I use CPVC because I know it works, stays in shape, doesn't burn up in
moderate exposure to RF (IE. less than 1500 watts) is inexpensive and
for what I do with it outlasts regular PVC plumbing pipe.

Now Lexan WOULD be better in the short term, but it disintegrates
rapidly in UV exposure, does not withstand thermal shocks well, distorts
in shape when heated, is harder to cut and machine and is much more
expensive. It is about 20:1 in cost, plus shipping as it is not
available locally here in the boondocks. I go to "Home Depot" and can
buy a stick 3 meters long for less than $10.00US, no shipping.

Hope this dispels any rumors about CPVC.

Well --

1. I remember reading in QST some years ago abut a home-brew mobile antenna that a fellow wound on gray PVC, and as soon as he tried to tune it up, the SWR was so unstable that he couldn't get a reading. Within about 30 seconds, the PVC got so soft that it bent over.

2. Roy, W5ROY, who lives here in Clovis, wound a mobile coil on gray PVC to build a screwdriver antenna. It would tune OK with the analyzer, but when trying to put 100 watts in it, it would be OK for only a few seconds, then would require retuning. He was using a set of plans of some sort, and he later found in those instructions where it said NOT to use gray PVC.

I'll research this some more and get back on this subject.

Just fill up as much of the yard as you can. I was lucky enough to have the bigger lot, but look at it like it is the metal on an auto. You know the ground metal on an automobile is smaller than 30X50ft. What this is equal to is a disk of metal that would be the size of your yard. My truck is 15'X9ft. It is elevated 2ft off the ground, but it works pretty well mobile. Your yard, with this much area would be like having a locomotive for area to mount the antenna on. Even with 5" squares of open space, it will appear to be a solid metal sheet at RF. If you bury this grid, it can be made to look really nice. Even laying on top of the grass wouldn't be to bad.

Just an idea.

You have an enormous amount of room... the dilema being that the more antennas you put in it the more they will interact. I would suggest you drop a pipe vertically from as close to dead center as you can and mount a tiny yagi like the Mosley Mini 33. That would give you great performance on 20,15 and 10 meters. They only need 9 feet of radius for turning room. There is also a cushcraft MA5B and a small Butternut which would fit. You might actually be able to get in a bigger yagi if you really have 32 feet of width everywhere. Then around the entire perimeter try a great big loop for lower band coverage.

But I'd also think about getting at least one inverted V up outside. I live in a "no antennas" community and have 3 wire antennas up in the trees... no one can see them, and the feed lines are all buried. My favorite all purpose wire antenna is the Buckmaster, which is ressonant on 75,40,30, 30, 12, 10 and 6 meters. Have a look on EHam.com for reviews. Another solution is to put a thin rope up into a tree and hoist one or more of the end fed vertical dipoles from Par. These are incredibly well thought of, and dirt cheap high performance antennas. You can also operate these temporarily using a 31 ft Jackite fibreglass pole... available on EBay.

All of these solutions will work much better than the common "portable" antennas.

RF in the house is a common problem with inside antennas... I'd take 10 minutes and put dipole up in the attic and try it before investing a bunch of time and money on the ultimate solutions. See how much of a signal gets into the TV, phones, computer speakers etc. An inside antenna may not be the wife solution if every electronic appliance in the house gets hot when you transmit.

As a last bad thought I've had ok performance from wires lying on top of roof shingles.

I was thinking about a 20M dipole just to test first....

And the area sounds bigger than it really is, the 6ft is only in the center....its a A frame truss...

What would a horizontal loop do for me there? Figuring two long sides of 48 ft and the short ends at 24 ft? I could get that in and not bang my head on too many nails that way!

30 x 40 feet? Try loaded radials.. Even Z shaped radials..?

To build these, make a dipole in the garden to fit, by inserting some coils and fiddle with them to get them approximately the right size (I have a 40m loaded dipole on my site as an example).

Once the dipole is finished in a size that will fit your site, convert them to radials by connecting them to the radial (earth) point on the antenna. Voila! You will then have resonant radials.

You understand?

Callum McCormick

Interesting. Loved your antenna project.

Some questions.
How long has it been up, exposed to the elements?
How much stress is there on the plastic, IE is it supporting anything external? My experiences with that type of plastic is it becomes brittle. When building traps for very long dipoles, you can have some very phenomenal stresses pulling on the form. You have the weight of the wire. I use #12, so this can be pretty heavy. Then you have the tension of stretching the wire taught so it stays up high without undue drooping. It also can have lots of other forces, such as wind during storms. We experience winds of over 40-50 MPH at times here and I have seen 90 MPH gusts during spring time. We also have lots of birds in the area. They love my wire antenna as a perch to roost on. Since I am handicapped and have to rely on others to do the physical work for me, so what ever I put in the air has to be minimal maintainence.

Just wondering what your experience has been with these added thoughts?

I was thinking about a 20M dipole just to test first....

And the area sounds bigger than it really is, the 6ft is only in the center....its a A frame truss...

What would a horizontal loop do for me there? Figuring two long sides of 48 ft and the short ends at 24 ft? I could get that in and not bang my head on too many nails that way!

Now we're back to my original question. I have a 2 meter j-pole above my roof that I built. I have a 1:1 BALUN, not a 4:1 BALUN, and it's pretty close to 50ohms. So, what's the 4:1 BALUN for?

Asked a friend of mine about white versus gray PVC, and here's what he
came up with --

> Here's how they measure it:
http://www.nikhef.nl/~h73/kn1c/praktikum/phywe/LEP/Experim/4_2_06.pdf
>
>
> Here's the info on most common plastics:
http://www.americanplasticsupply.com/properties.html Click on the sheets, and they
enlarge. You can also search for one specific plastic if you wish.

Boiling it down to something simple --

> The gray PVC has a filler which is uses to retard UV, and some acidic soils. It is good
to about 100 MHz, where it starts to get rather warm. The white PVC is good to about 400 or
so. The black OVC won't do 10 MHz very well.
>
> Natural Delrin (sort of milky color) it good to about 3 GHz.
>
> Natural Nylon (it too is milky) is good to about 1.5 GHz.

Drawing dates are Nov 2006, so going on two years... 2 winters so far.
No signs of brittleness yet. It is LDPE and in black, so don't really
expect any UV degradation, at least not for a long time. The coax
jacket will probably go to pot along the way.
No stresses... it is only a form to wind the balun on.
Not like a trap in an element.
RG-8X coax, 7.5 turns, secured with black all-weather cable ties.
Don't know if it really does any good, but things seem to work OK.
20ft boom 13-element 2m yagi. Common dipole for driven element.
Dimensions from ARRL Antenna Book.
It can hold a LOT of birds! $&##@!!@#(&
They also like my G5RV with 75ft of horizontal feedline.

I'm not handicapped, just getting too old to climb towers. My 45ft
tower is hinged at the base and lowered via winch & cable.
Planning on another tower some day when I can figure out where to put
it. I only have 80acres to chose from!
Thanks for the note.

6011. 43 foot long multiband verticals - what is the theory behing them?

Yahoo group: ham-antennas (2008)
Date: 2008-09-21 00:56:11 UTC
From: billncolo36
Topic: 6011 Message: 6011

Multiband operation (with a tuner) without traps, tuning stubs, etc. Several manufacturers offer them and they seem to work fairly well (at least the ones I have listened to). Does the 43 foot length plus a 4:1 balun simply make it so a good tuner can deal with the impedance seen on each of the bands?

I knew all that stuff, I just didn't think it was applicable to what
we were discussing. CPVC Sched 40 is not to expensive but the
connectors seem kinda pricy.

Well Earl, I think you just said what I was saying. CPVC is the choice for temperature excursions and UV resistance. White or PVC gets damaged by UV, becomes brittle with oxidation and UV exposure, breaks or falls apart. At HF (30 Mhz and below, you can use either, or, and accept the degradation for PVC or use CPVC, get up to 3 to 5 times the life. My present antenna, Trapped dipoles for 160/75/60/40/30 has been up since I moved here from Albuquerque, 2002. Before that, I rebuilt my PVC dipole every year. Kept falling apart.

As pointed out in the papers, the Dielectric constant is so minimal (.0002% at 1 Mhz) that even if you draw a linear interpolation chart, with 100% being at 2.7 Ghz, 30 Mhz and below is not a factor since we are still talking about only .0005% absorptive. At 1000 watts RTTY the forms would at max would be trying to dissipate 50 Milliwatts, and at the size of my forms (about 5" long and 2" diameter) there would be more solar radiation than from my amateur radio signal. But, if a coil's Q is low, and is used at certain frequencies where it becomes self resonant across the shorted turns, as in a screw driver antenna not designed correctly, the coil will get warm... enough so that the plastic (CPVC or otherwise) can become damaged. I have seen this at 21 Mhz in an

amplifier that the builder tried to use PVC pipe as a form, and with #10 wire, actually caught fire in only a few seconds. This was a pair of 572B's with only 2200 volts and around .5 amps plate current. You wouldn't think that the coil this large could get hot enough, but the solder joints melted. All this in less time than a blow torch could have done an equal amount of damage. Changing the coil configuration so that no coil turns were shorted, just tapped, fixed the problem, and the amp then happily produced 700 watts PEP output.

I have worked with, and am in fact working now with attic antennas. The one thing to worry about is RF gets into everything, TV, phone, etc., but I'm sure you already know that.

You've got alot of space to work with there, which is great. You may want to try a skyloop, a large horizontal loop fed with balanced line to a tuner. With 48x32 feet, that's 160 feet of wire you can get up there, which might get you on to the 40 meter band. You may also want to try an open loop, in which the loop is open at the end opposite the feedpoint, kind of like a dipole but bent into a rectange. I'm using that design right now and the results have been OK so far, although not the greatest.

Another thing you can experiment with is a dipole. If you bend the ends downward, you'll be able to get around 60 feet of wire up there, which is shorter than 40 meters but again with a tuner, it should load there. If you just want to do a flatop, you can probably get 46 feet of wire up there for a 30 meter dipole which when fed with balanced line, should should be able to load up on all the bands 30 meters and above.

And endfed zepp might also be an option worth exploring. Learn what you can about antennas from whatever source you can, like this list, the WWW, books, etc., and I'm sure you'll come up with something that will work well for you.

I've worked with various antennas in my attic over the years, such as a random wire, dipole, the half wave open loop I have now, and even a commercially made AEA Isoloop(similar to the MFJ SuperLoop) and had mixed results, but at least I was, and still am, making QSOs off my attic antenna.

In addition to RF getting into stuff, another problem I've experienced with attic antennas is they don't always perform when the roof is wet. Sometimes when the roof is wet, some antennas which may load flat everywhere, will not load at all or as well when the roof is wet. I sometimes get reports my signal isn't as good, or I don't receive as well under those conditions. Perhaps the water makes the roof conductive. In spite of all this, at least I'm on the air making QSOs.

These days, I spend alot of time on PSK31 20, 30, and 40 meters, and haven't had as many RF problems as I've had with CW and SSB. Don't know if that is just luck or something about the mode, which is why I spend most of my time on it these days.

Good luck, get an antenna up there and get on the air!

6016. Re: How many radials are needed on the roky-sand soil to inatall multiband vertical?

Yahoo group: ham-antennas (2008)
Date: 2008-09-21 04:31:42 UTC
From: ash_lee52
Topic: 5969 Message: 6016

I live on very dry rocky soil... and basically even with elevated radials the soil makes verticals perform much worse for me than they did on the black soil of the midwest. There is just no reflectivity in the dry rocky soil.

An antenna such as a Hustler 6BTV will "work"... you'll have lots of QSOs... as long as you have 2 radials per band and minimise contact with the soil (remember desert soil isn't very conductive so a little contact doesn't mean much). But you will get way better performance from wires in the air and/or horizontally polarized antennas. I've modeled very low yagis over dry soil and while yagis always benefit from height, a low yagi will still strongly outperfrom a vertical over dry soil.

For one simple solution look into the Buckmaster antenna. It sets up as an inverted V with an apex at 35 feet, and is resonnant on all the bands 80-6 meters except 15. With a tuner you can get it to work on both 160 and 15 meters. It doesn't get much easier than that... and mine does much better than my 6BTV... particularly by being much quieter.

Another fairly easy fix is to use a "no radials needed" antenna such as a Cushcraft MA5V (needs to be mounted at least 10 fee off the ground), a Sigma 5 or a Par end fed Vertical dipole. None of these will work as well over rocky soil as on an island in the pacific. But they will work pretty well. None work for me as well as the Buckmaster however.

You asked about using the MFJ259B... not much to it... just stick it on the ground and touch only the plastic knob when checking the antenna. It'll be close enough.

Thanks Jonathan:

Yes RF is expected in everything, but Ill operate mostly when XYL and kids are away anyway.....Im sure a mushroom cloud would be created if I interfered with a episode of Hannah Montana!!!!

I have the audio cables made and software loaded for PSK31, thats my next project to complete, probably next week!

One thing I plan on testing is my vertical stainless stove pipe. Its about 40 ft and with a tuner who knows!

For UHF/VHF Ive already looked at one of the discuise antennas for a vent pipe.

Thanks for all the ideas!!!!!

OMs,
I live in pyramid shaped roof single (ground floor) story house.
I experimented with few indoor antennas and promptly "discovered" that any electronic gizmo will go wild with RF - including my wife's paper shredder!

However, during my experiments I noticed almost zero signals on the band.

My roof sheathing is the "flame retardant" variety - plywood covered inside of the attic with silver "stuff". I am assuming it is metal. I do not know.I did not test it for conductivity. (Unless it is made from Teflon it would not be too much of a flame retardant.)

I am seeking opinions / experience / comments from anybody who is using attic antenna under this flame retardant / heat reflecting setup.

Having modelled those and seen some in action, they are fairly good
above the lowest frequency for which they are a half wave

Below that, efficiency drops fairly rapidly. But even a low-
efficiency antenna can sometimes get the job done.

Hello,

A few days ago i installed a vertical multiband antenne from diamond the BB7V, but i am not happy with iat at this moment, i receive alot of QRM, (s7) and a big repeating hum sound (from 14 to 18 Mhz). Are there any users in this group that also use this antenne, and how do they like this antenne.

The reasson that i bought this antenna is due to the fact that i only can plant verticals without radiasl, du to the small space i have.

Perhaps someone of this groep can and will advice me.

Thanks

With the 4:1 balun, you get a little wider bandwidth.

The 200 point is easier to find than is the 50 point.

6028. 2m beam question

Yahoo group: ham-antennas (2008)
Date: 2008-09-22 19:40:01 UTC
From: Mark Blanton
Topic: 6028 Message: 6028

I've been a ham 26 years but have little VHF weak signal experience. Last week I purchased and Icom 746Pro with 2m all-mode capability. I have a tower with a 3-el tribander and 2m Ringo Ranger vertical. Was wondering if I could put a horizontally polarized 11-element 2m beam just below the Ringo (and above the tribander) without any crosstalk between to two 2m antennas? I could take the Ringo down and put the beam in its place but really want to keep the vertical up there for repeater coverage. I realize I may be trying to have my cake and eat it too, but comments and recommendations are appreciated.

From: Angus
Topic: 6028 Message: 6029

Mark the antennas will be 90degrees out of phase with each other which is good, there will be some crosstalk but possibly not worth worrying about (I guess your going to dwitch between the yagis with either a coaxial switch or coaxial relay), unless your going for very weak signal stuff and if you where you might have a lot more 2mtr yagis up.
Put up the yagi and keep the vertical and enjoy both worlds of 2mtrs (FM, SSB)
good luck
regards
Gus M0IKB

No problem with that because they will have different feed lines.

From: vaclav sal
Topic: 6028 Message: 6032

It theory the radiated fields are 90 degrees "out of phase " and the "crosstalk" (I am not so sure we are using the right term here) would be none. In practice the attenuation is somewhere in 20 to 30 db range.

However the interaction between the antennas would only be a problem if you are planning to use them in full duplex operation and on same or close-by frequency.

In early sixties Czech military was successfully using polarized Yagis in 400 MHz range in point to point communication. The link had different polarization for transmit and receive and worked as full duplex channel operation. I do not recall the "channel" frequency separation, but it carried three audio channels without any crosstalk.

From: Randy McKenzie
Topic: 5988 Message: 6033

I watched a home improvement show and they were using a sheathing material that had a layer of foil, and claimed the foil was to reflect the UV rays and not allow them to enter the house. Maybe this is what you have?

My roof is asphalt shingles, plywood and a metal ridge vent. Ive already explored the idea of seperating the center section, bonding each joint and using the metal as the dipole! Its AL, and I expect it would be pretty broad band considering its size.....

Mark:

You should be fine. Seems like the figure was 60db of "isolation" between horizontal and vert.....seperate feedlines and some space will let you have both.

Ive seperated commercial VHF on towers vertically and they dont hear each other even with some close spaced duplex channels.

If you do have some issues, try lowering the bottom antenna a few inches, sometimes youll find a "null" and they dont even see each other. VHF is funny that way.

I recently purchased a Yaesu 857 and hope to play with some SSB on 6M and 2M, never used that mode on those bands, should be some fun!

I have found that many items at garage and yard sales can be ham related, but the seller has no clue what they are or what to price them at. This weekend was a good weekend for me (I am a junkie). I found coax for nothing, a box of galvanized clamps for $2.00 and a rotor for a buck. Not working? junk it. Works--great deal for me. What I got was an Alliance Tenna Rotor, model U-110 head (only) It is a four wire unit. It says the Genie Company on the tag. It's the old "click..click..click" type. Any ideas on the motor, or instructions? Don't know if I wasted a buck, but I spend that much in pop during work.

Hello eveyone,
New member here.
I am looking for a manual for an older Hy-Gain VB-66DX. It a 6 meter 6 elm on a 25 ft beam. I want to make sure it is a 66dx and it is set up correct. It is missing the center that joins the two beam sections together and mounts it to the mast The manual on the web site is for a newer model. I talked to there tech service and they do not have one.
If anyone has any info it would be great.
Thanks in advance.

From: Dave, K2DP
Topic: 6035 Message: 6039

HI Ken,

I have replaced the lamps in the 2800 with the exact replacement from Yaesu. Not exactly a "serviceable" item as you need to completely disassemble the rotator control unit, get to a printed circuit board that is buried beneath and behind others, and then un-solder the lamp leads from the board and replace with the new lamp.

A real pain in the neck considering the ease with which you can replace the lamps in the CDE rotators. On the other hand, we have had the 2800 in service for 9 years now with a very large Force 12 C36XR antenna and assorted VHF beams and have had no problems with the rotator itself !

Hi Dave,

Thanks for the bad news! 8*)

I had started to open the box up and have a look and finally realized that I was going to have to completely disassemble the thing in order to even have a look at the bulb. That's when I put everything back together and posted my first message. I guess I'll just wait until I do have trouble with it then take it completely apart, measure the voltage at the bulb, do the resistance calculation and replace it with a wide angle white LED.

Thanks again for the information.

Hi Dan
?I know we have talked before about the antenna. I pulled the t-6 log down and sold it last week,just too big 40' elements, too hard to drop the tower for me and the xyl, each time it looked like a storm might hit around here. I tried a gap titan ,wasent impressed at at all ,plus the ant swayed all over with out guys,really badly. I kept the tilt base and would use it with the 640, if I go that way. I guess I should look at your , said that a few times before ,somehow never made it. Ive finally stopped and fully retired from Carrier so have lots of time now. Let me know when you will be around,this time I will make it.to look at the 640.
thanks

Does anyone in the group have any real life opinions about this antenna? I have no room for any vertical that requires radials,need a counterpoise antenna. I have tried the gap titan,and the r-8,ok but not great. I have heard the 640 was a good performer for a vertical.
?? Looking for any and all opinions.
thanks

From: Wade
Topic: 5988 Message: 6046

Randy, I've spent the better part of a year and a half experimenting with different stealth antennas. I love the Ventenna for 2M/440. I even sent in some pictures to the mfg. if you want to look at them:

http://www.ventenna.com/Stealth.html

As for HF, man I've tried just about everything. I've got a 40 meter dipole in the attic fed by 450 ohm window line. I use an MFJ Intellituner to drive the balanced antenna. It works on every band from 40 to 10.

I tried an SGC autocoupler in the attic and elsewhere around the property but was getting too much noise.

I also have 20, 40 and 80 meter dipoles affixed to a six foot wooden fence in the backyard. They work surprisingly well, and despite the low elevation I work a fair amount of DX.

You might also consider a Buddipole for use while you're operating, then simply take it down. I use one on a 20 foot painters pole when the DX is good and I find it works better than anything I've got for 20 meters.

Hope this helps.

Wade

From: swlstation
Topic: 6047 Message: 6047

Hello,

I have the following question, i have a vertical antenne for HF (diamond bb7v) and a wellbrook RECEIVIN loop, due to the fact that i receive a lot of QRM on my vertical i would like to do the following, receiving on the loop and transmitting on the vertical.

Is this possible and how to do this ??

any advice is welcome.

thanks

ron (pd1anb)

Depends on the radio. FT1000MPs (for instance) have a receiving jack that the user can select. It will switch automatically.

You may need a manual coax switch or perhaps build a simple footswitch assembly triggering a coax relay or similar.

Cheers,

Callum McCormick

If your radio doesn't have a dedicated port for a receive antenna you will needs some sort of antenna switch. A electronic Coax switch and using the T/R Line for a Amp would make it pretty automatic.

Hello Ron- Some of the HF rigs have two antenna connectors (or more)
on the rear apron for this provision - what rig are you using? Otherwise
you could probably wire in a Dow coaxial Key - and I am sre there are
several others, Dow just came to my mind - Dave N?ATH

I am also thinking of buying this antenna. I've heard it is a good one. I need to mount it on my roof and was thinking of using a short tripod tower like the one sold by Bencher for their veriticals. Only problem I see is the lack of 80 meter coverage. Does anyone know if it would help to add radials in addition to the counterpoise that is part of this antenna?

Thanks,

Vee W7IBB (Utah)

I have been using this antenna for 3 yrs. Works great.

DO NOT add radials. They serve no purpose. It may actually degrade the operation and raise the SWR.

DO NOT elevate it more than 8 feet. There is no advantage.
It will not work on 80 meters.

Dan,

Do you have this ground mounted on an 8' mast or roof mounted?

Vee

I have been using this antenna for 3 yrs. Works great.

DO NOT add radials. They serve no purpose. It may actually degrade the operation and raise the SWR.

DO NOT elevate it more than 8 feet. There is no advantage.
It will not work on 80 meters.

Best Regards
Dan Schaaf

Subject: [ham-antennas] Re: HY-GAIN AV-640 VERTICAL

I am also thinking of buying this antenna. I've heard it is a good one. I need to mount it on my roof and was thinking of using a short tripod tower like the one sold by Bencher for their veriticals. Only problem I see is the lack of 80 meter coverage. Does anyone know if it would help to add radials in addition to the counterpoise that is part of this antenna?

Thanks,

Vee W7IBB (Utah)

For all and Callum I miss-posted now. My laptop and desktop PC were
dead and send e-mail by anothe place.
sod I could not reply anyone who kindly to advice me many thing.

Callum I tried multiple trap verticals and saw your great site to
learun ground,radial systems.
I had already tried Z -shape radial placed on the rocky -sand though,
that was failed to match any band.
So I think the amount of radial is insufficient.
I know the difference of the resistance between 32 radials and 8
radials but Cu wire costs too expensive so I am looking forto get them
in low cost. #26-18 AWG sounds real to me
but I will try 32 radials, Thanks Cullum and if any additional advice
to me I am very appreciated.73 Tim

Steve I am sorry to reply too late.my laptop pc works too bad now.
it is going to be buriied.
Well thanks for your good idea.
As your advice altered the iron screen at the same square of my
vehicle, I can understand it soon.
As quoted from your advice, 5"square is right?
I tried 5feet square metal grid on the rocky-sand,
but did not resonate or got any correct field data
of multiband trap vertical.
TU 73 Tim,

I think you are saying that your antenna modeling software isn't showing
you correct figures?

What you should see is that with 125MM square steel wire and 15 to 16
meters X 15 to 16 meters of coverage, you should be able to make your
vertical work pretty good. It will be about 10 X better than a car
mounted antenna. It will not be perfect, but should work really nice on
40 - 10 meters, and you should be able to match up an 80 meter pole.

Hiash, ashton,
I am sorry to say my reply is too late because of my laptop PC
went to heaven.
Well thank you for your advice.
I know your very much rocky-area has to choose very resitriced antennas.
I know. the coral block place of my lot is like your place, too.

> did on the black soil of the midwest. There is just no reflectivity
in the dry rocky soil.
I think, from my portable operation on the rock operation,
with 16 radials #14 copper wire resonated at the bottom band
worked well intercontinental QSO and Atlantic path.

> An antenna such as a Hustler 6BTV will "work"... you'll have lots of
QSOs... as long as you have 2 radials per band and minimise contact
I failed 2 radials per band everytime. Radials is expected to
be more than 8 but on some band like 40m and 15m, as you know
40m radials resonate on 15m band so to operate on 80,40,20,10
8x4 is 32 radials were needed.
> with the soil (remember desert soil isn't very conductive so a little
> contact doesn't mean much).
Certainly,
But you will get way better performance
> from wires in the air and/or horizontally polarized antennas. I've
> modeled very low yagis over dry soil and while yagis always benefit
> from height, a low yagi will still strongly outperfrom a vertical
over dry soil.
I thinks so. the full size dipole or inertedV is the final way
at the IOTA operations.
> For one simple solution look into the Buckmaster antenna. It sets up as

> Another fairly easy fix is to use a "no radials needed" antenna such
as a Cushcraft MA5V (needs to be mounted at least 10 fee off the
ground), a Sigma 5 or a Par end fed Vertical dipole. None of these
will work as well over rocky soil as on an island in the pacific. But
they will work

I love Sigma antennas for Sigma5 and Sigma40 with homebrew tuner.
it works very well but the bottom element is lower , the better
peformance we get.Why does MA5 should mount at least 10 feet high?
Let me know.

> You asked about using the MFJ259B... not much to it... just stick it
on the ground and touch only the plastic knob when checking the antenna.
Sure I did ash, but body effect caused VSWR or IMP lowered.

So other people advised me to make choke coil and keep out
the radial placed area. so I never measure them in the area of
radials.
Tim,

6063. OCF dipole question

Yahoo group: ham-antennas (2008)
Date: 2008-09-25 10:55:55 UTC
From: lecontejoe
Topic: 6063 Message: 6063

A couple of days ago I erected an off-center-fed dipole for 80, 40, 20, and 10. Uses a Balun Designs 4:1 balun:
http://www.balundesigns.com/servlet/the-56/current-balun-4-cln-1-designs/Detail

I built the antenna to these dimensions:
http://www.wcerc.org/Projects/ocf_dipole.asp

One leg is 86' 2-1/2 inches, the other is 46' 9-1/2 inches.

The balun is attached to a PVC vent pipe coming out of the roof of my house about 20 feet off the ground. The short end runs to the garage and terminates about 10 feet off the ground while the long end runs to my workshop and terminates about 15 feet off the ground.

My MFJ analyzer shows SWR to be:

-- 2.5:1 - 3:1 across 80.
-- under 1.75:1 across 40
-- 3:1 at bottom and top of 20, under 2:1 most of the rest of the band
-- 1.5:1 - 2.5:1 across 10

I'm runnning an FT-857D with FC-30 automatic tuner. The rig does what I expected -- at points where SWR showed around or over 3:1 on the MFJ antenna analyzer, the tuner tries to tune the line then shows high SWR warning and shuts down the transmitter.

I noticed when checking the antenna with the analyzer that resonances with 1:1 matches appeared at:
4.25 MHz
7.175 MHZ
14.5 MHz

Now -- if I add a couple of feet of wire to each end of the antenna to bring resonance down to inside 80 and 20, what's going to happen to resonance at 40 meters? Seems as though that would drop below 40.

Weather is bad right now but I'm thinking when it clears up I'll cut two lengths of wire, 3 feet, solder to alligator clips, clip onto the ends of the antenna and see what happens.

Or -- is the antenna too low to reach any kind of resonance on 80?

Thanks.

6064. Re: [ham-antennas] OCF dipole question

You will just have to try it.

In addition, another thing that you could try is adding a bit of wire to one end or the other only.
Also you could try adding wire to one end and shortening the other as though you were sliding the feedpoint one way or the other.

You could go to <http://www.eznec.com> and get the educational version
to model your antenna to see what it can do. You should be able to see
exactly what is happening in your situation. Better than playing on a
slippery wet roof.

6067. Re: [ham-antennas] OCF dipole question

Yahoo group: ham-antennas (2008)
Date: 2008-09-25 19:34:14 UTC
From: Charlie the Swen
Topic: 6063 Message: 6067

I live in a mobile home court and only have the space over my home to put an antenna. I was thinking about this "AI4JI's Off-Center Fed Dipole / Windom Antenna" OCF but was wondering what would happen if I made it half as long. I supose I would also need to adjust the length a little because I am shortening it. (not exactly half) I will probably eventually want to work 80m but Buckmaster seems to think that 40-6 all work fine on their antenna that is half that long. That would fit because I only have 64 feet to put the antenna. The off center would work because my shack is located about 20 feet from the front of the 66 foot mobile home. I am wanting to build my own, as I feel that is part of the "fun" of being involved in Ham Radio. Just got my general license this summer. I am using a TS530 Kenwood with an AT230 Kenwood tuner and an external SWR meter so I can monitor the SWR and not fry something. I will be only using low wattage, under 300. I suppose that I am also waiting for the really foul weather to install an antenna as I understand that they work much better if you suffer a little in the installation.

Ron,
If your radio does not support 2 antennas that is capable to use one on tx and one on rx on the same band,
The second option would be an external TR relay to switch antennas.

Sorry for the extra information, but i am using a YASEU FT-897d, this
one has 2 antenne inputs, only one is used for VHF/UHF

have you considered the roof of the mobile home ? fiberglass or metal if metal it will act as a reflector .. how high are you able to go above the home ? lots of things to consider , a vertical might be better using the roof as a ground plane.

Subject: Re: [ham-antennas] OCF dipole question

I live in a mobile home court and only have the space over my home to put an antenna. I was thinking about this "AI4JI's Off-Center Fed Dipole / Windom Antenna" OCF but was wondering what would happen if I made it half as long. I supose I would also need to adjust the length a little because I am shortening it. (not exactly half) I will probably eventually want to work 80m but Buckmaster seems to think that 40-6 all work fine on their antenna that is half that long. That would fit because I only have 64 feet to put the antenna. The off center would work because my shack is located about 20 feet from the front of the 66 foot mobile home. I am wanting to build my own, as I feel that is part of the "fun" of being involved in Ham Radio. Just got my general license this summer. I am using a TS530 Kenwood with an AT230 Kenwood tuner and an external SWR meter so I can monitor the SWR and not fry something. I will be only using low wattage, under 300. I suppose
that I am also waiting for the really foul weather to install an antenna as I understand that they work much better if you suffer a little in the installation.

Charlie,

Bismarck, ND? "...waiting for really foul weather...?" You only have about 25 minutes of summer there don't you. :-) I grew up in Sioux City, IA so am fairly intimate with the weather out that way.

I am curious about what would happen if you made a big rectangular open loop off all four corners of your home? Maybe the legs would be too close together but I would love to get some opinions. I also wonder what effect the metal mobile home, assuming it is metal, would have.

From: Charlie the Swen
Topic: 6063 Message: 6071

I have thought of the loop. If that was 132' and it went from corner to corner on the 14'X66' roof there would be a 28' gap between the ends of the loop. I don't want the thing to look too "antenna", maybe I can say that it is just my attempt to make a digital TV antenna. I was thinking that the OCF would be a little less obvious. I have also thought of a Z formation using 132' of wire, although I have heard that the Z isn't as effective as the loop or the inverted V dipole.

I suppose that is the problem with opinions is that they are just that..... opinions.

Would the loop have to be horizontal; how far would it have to be from the metal roof and siding and would that become some kind of couterpoise? The biggest problem with this is that the best way to find out is to put one up and see what happens.

Oh, yes, Summer is already over.... but fall can be really nice....

Separate Transmit/Receive Antenna Switching
Phil Salas ? AD5X

Introduction
There are times when it can be beneficial to use separate antennas for transmitting and receiving. As an example, a vertical antenna can be a great radiator on 160 and 80 meters, but it may also be a very noisy receiving antenna. So maybe the low-noise characteristics of a magnetic loop antenna or a beverage antenna may sometimes be desired for receiving. Now many higher-end transceivers have a separate antenna connector for a receive-only antenna. But my IC-706MKIIG, like most low-to-moderate priced transceivers, does not. However, it is not difficult to provide separate T/R antenna switching externally for most radios.

Design Consideration
The T/R antenna switch uses a relay for antenna switching, under control of the amplifier interface available on most transceivers. Since lead lengths and their associated inductances are very forgiving at frequencies below 30 MHz, the important thing becomes the current rating of the relay contacts and the relay switching time, as it is important for the relay to fully energize before your transmitter puts out power. The heart of this unit is the Fujitsu 10-amp SPDT relay called out in the parts list (Table 1). This relay has a specified maximum switching time of 10 milliseconds. I measured the HSEND-to-RF Output on my IC-706MKIIG as 12-15 milliseconds from start of the output RF to full RF power. So the 10 millisecond switching time of this relay is perfect for this transceiver.

The Circuit
Figure 1 is the schematic of the antenna switch. The relay driver interface is pretty generic and should work with most transceivers that provide an open-collector transistor to ground for enabling an external amplifier. On the IC-706MKIIG, the HSEND output is a bi-directional output that must only drive a high impedance load, and should not be pulled up higher than 8-volts. For most other transceivers you can just connect the +8V point to a +13.8V input as is shown by the dashed line on the schematic. The LED shows when the TX antenna has been selected. You can add a SPST switch in series with the either the +8 or +13.8V inputs to disable the switch when desired. I found it just as easy to unplug the interface cable to the transceiver when the separate antenna switching is not needed. I used SO-239 connectors for the RF interfaces, and a Molex 4-pin miniature

connector for the control signals. All circuitry is wired on two terminal strips. The relay and LED are mounted by hot-gluing them to the bottom of the aluminum box. Photos A and B show the inside and outside of the transmit/receive antenna switch.

Conclusion
I?ve described a simple external antenna switch for separate transmit/receive antenna switching. If your transceiver doesn?t have a separate receive-only antenna connector, this switch will inexpensively solve this problem.

Separate Transmit/Receive Antenna Switching
Phil Salas ? AD5X

Introduction
There are times when it can be beneficial to use separate antennas for transmitting and receiving.? As an example, a vertical antenna can be a great radiator on 160 and 80 meters, but it may also be a very noisy receiving antenna.? So maybe the low-noise characteristics of a magnetic loop antenna or a beverage antenna may sometimes be desired for receiving.? Now many higher-end transceivers have a separate antenna connector for a receive-only antenna.? But my IC-706MKIIG, like most low-to-moderate priced transceivers, does not.? However, it is not difficult to provide separate T/R antenna
switching externally for most radios.

Design Consideration
The T/R antenna switch uses a relay for antenna switching, under control of the amplifier interface available on most transceivers.? Since lead lengths and their associated inductances are very forgiving at frequencies below 30 MHz, the important thing becomes the current rating of the relay contacts and the relay switching time, as it is important for the relay to fully energize before your transmitter puts out power.? The heart of this unit is the Fujitsu 10-amp SPDT relay called out in the parts list (Table 1).?
This relay has a specified maximum switching time of 10 milliseconds.? I measured the HSEND-to-RF Output on my IC-706MKIIG as 12-15 milliseconds from start of the output RF to full RF power.? So the 10 millisecond switching time of this relay is perfect for this transceiver.? ?

The Circuit
Figure 1 is the schematic of the antenna switch.? The relay driver interface is pretty generic and should work with most transceivers that provide an open-collector transistor

to ground for enabling an external amplifier.? On the IC-706MKIIG, the HSEND output is a bi-directional output that must only drive a high impedance load, and should not be pulled up higher than 8-volts.? For most other transceivers you can just connect the +8V point to a +13.8V input as is shown by the dashed line on the schematic.? The LED shows when the TX antenna has been selected.? You can add a SPST switch in series with the either the +8 or +13.8V inputs to disable the switch when desired.? I found it just as easy to unplug the interface cable to the transceiver when the separate antenna switching is not needed.? I used SO-239 connectors for the RF interfaces, and a Molex 4-pin miniature connector for the control signals.? All circuitry is wired on two terminal strips.? The relay
and LED are mounted by hot-gluing them to the bottom of the aluminum box.? Photos A and B show the inside and outside of the transmit/receive antenna switch.

Conclusion
I?ve described a simple external antenna switch for separate transmit/receive antenna switching.? If your transceiver doesn?t have a separate receive-only antenna connector, this switch will inexpensively solve this problem.?

Hello Everybody,

I picked up 5 sections of a tower. 4 sections look like the size of 55g and the other looks like 25g. It is very well made and heavy. They are 10' long and have 8 rungs.
Foot print on the larger size is 18 3/4 center to center, smaller size is 10 1/2 . I will upload some pictures. Any help would be great. I am lookng for the spec or any information.
Thank you in advance.
